INDEX.

Abortion—Treatment of, 423.
A Case of Living Xiphopagus, 28.
A Case of Pneumonia with Remarks, Kempf, E. J., 894.
A case of Diphthretic Croup in which a Tracheotomy Tube was worn for sixty days, Wharton, H. R., 923.
Abscess of Frontal Sinus, Wall, G. A., 166.
Abuse of Milk in Albuminurics, 345.
Acne, 301.
Actinomycosis Hominis, 158.
Action of Chloroform upon the Human Being, 308.
Acute Forms of Gastric Hyperasthemia, 746.
Intestinal Obstruction—Treatment of, 545.
A Discussion of the Legal Aspect of Criminal Abortion, Porter, William W., 655.
Administration of Chloroform and Its Dangers, 103–624.
Of Ether for Surgical Operations, Morris, Ellis-ton J., 569.
Advantages of Antiseptic Irrigation of Parturient Canal Before and After Labor, Barker, T. Ridgway 845.
Address on Hygiene, Dixon, Samuel G., 876.
After-effects of Chloroform, 913.
After Effects of Chloroform, 273–420.
Albuminuria During Pregnancy, 108.
All That is Necessary, 211.
American Medical Association, 930-962.
Amputation at the Hip; Re-section of the Rib, 171.
At Hip Joint: Encysted Cartilaginous Tumor near Subclavian Vessels; Operation on the Fifth Nerve, 691.
Anæsthetics—New Local, 516.
Aneurism of Cheek, 540.
Animal Extracts: Mode of Preparation and Physiological and Therapeutical Effects, Hammond, William A., 243.
Anti-Cholera Vaccination, 703.
Anti-Syphilitic Treatment—Proper Duration, 273.
Aortic Aneurism by Electrolysis Through Introduced Wire—Treatment of, 155.
Appendicitis, 77–116–292–697–824.
Medical and Surgical Management, 107.
Plea for Early Surgical Treatment, Cordier, A. H., 1.
Apotheosis of Dirt, Link, Wm. H., M. D., Petersburg, Ind., 319.
Apyretic Scarlatina, 861.
Aristol, 39.
Armour Institute, 359.
Arsenical Treatment of Multiple Sarcomatosis of the Tegumentary and Mucous Surfaces, 754.
Artificial Induction of Labor, 698.
A Short Umbilical Cord, Carroll, J. B., 132.
Aseptic and Antiseptic Care of Lying-in Woman and New-Born Child, Norton, H. G., 16.
Asepsis and Antisepsis in the Lying-in Chamber, 155
In Obstetrics, Mitchell, 366.
Attempt to Make a Radical Cure in Three Cases of Hernia, Wright, J. S., 168.
Aural Symptoms of Neurasthenia, 153.
Auto-Suggestion—The Kitsune-tsuki, 185.

Bacteriological Notes, 945.
Bacteria of the Stomach, 590.
Bi-Lateral Oophorectomy for Cure of Osteomatacia, 466.
Bacillus Coli Communis in Inflammatory Affections of Anus, 705.
Of Eclampsia, 516.
Birth in the Coffin After Maternal Death, 621.
Biology of Cholera Bacilli, 908.
Bow-legs, 595.
Black Eye, 87–545.
Bleeding Fibroids and Endometritis, 435.
Brain Syphilis, 495.
Brittle Bones, 589.
Bubo, 332.
Bugs and Bug Poisons, 291.
Burns of Conjunctiva by Instillation of Calomel, while giving Potassium Iodide Internally, 194.

Can a Septic Bullet Infect a Gunshot Wound? 78.
Cancer of Œsophagus—Rupture into Thoracic Cavity, 541.
Carbolic Acid in Surgery, 515.
Carcinoma—Mammæ, 492.
Thyroid Gland, 507.
Uteri, Montgomery, E. E., 10.
Cardiac Stimulation in Pneumonia, 370.
Stimulation in Pneumonia, Larrabee, John A., 364.
Caries of the Coccyx, 154.
Cæsarean Section for Eclampsia, 347.
Case of Cerebral Surgery, Dugan, W. C., 130.
Poisoning of Methyl Blue, 66.
Catarrhal Nephritis in Syphilis, Tuberculosis and Leprosy (Lepra), 181.
Sore Throat—Treatment of, 40.
Cautionary Facts, 754.
Cerebral Concussion, 177.
Syphilis, Hays, J. E., 86.
Spastic Paralysis, Willard, DeForrest, 762.
Certain Forms of Septicemia Resulting from Abortion, Currier, Andrew F., 214.
Cervical Stenosis, by Bi-lateral Discission—Treatment of, 744.
Chloroform as a Hæmostatic, 914.
Chloroform Anæsthesia and Its Administration, Gunterman, P., 806.
Anæsthesia and Its Administration, 851.
How to Administer Properly, 515.
Internal Uses of, 39.
Cholera, Epidemic of 1892, 29.
Cholecystotomy, 889.
Chronic Articular Rheumatism, 821.
Inversion of Uterus, Brasius, W. L., 446.
Pulmonary Phthisis in Later Adult Life, 433.
Clean Cistern Water, to, 112.
Clinical Observations in New York, Link, W. H., Petersburg, Ind., 927.
Clinical Classification of Hip Disease, 116.
Contributions on Intestinal Occlusion, 784.
And Experimental Contribution to Treatment with Creasote of Pulmonary Tuberculosis, Albu, 89.
Investigations Regarding Enlarged Thyroid and Operations for Relief, 702.
Observations in New York, Link, W. H., 681.
Club Foot, 68.
Coagulability of Blood in Parturition a Factor in Occurrence of Postpartum Hemorrhage, 670.
Cocaine Antidotes, 76.
Cocaine Antidotes, 913.
Cocillana, 316.
Cod Liver Oil in Rheumatics—Use of, 76.
Coffee as a Cause of Itching, 404.
Cold Bed, The, 223.
Congenital Club-foot, 821.
Syphilis, 114.

Consumption Caused by Cows, 671.
Continued Administration of Digitalis, 667,
Contributions to Pathology of Psoriasis, 829.
Correct Gymnastic Positions, 67.
Country Physician, The, Holmes, John C., 336.
Criminal Abortion, Parish, Wm. H., Jr., 644.
Responsibility in Early Stages of General Paralysis, Norbury, Frank P., 44.
Cry of Children, the, 913.
Croup Treatment, 433.
Cuneihysterectomie—New Operation for Flexion of Uterus, 385.
Curette in Obstretric and Gynecological Practice, Cecil, Jno. G., 50.
Cutaneous Cicatrices of Syphilis, 627.
Cystic Goitre with Cases in Practice, 953.

Dandruff Cures, 404.
Death in Infants from Hypertrophy of the Thymus, 464.
Deaths Under Chloroform, 196.
Decidua in the Diagnosis of Extra Uterine Pregnancy, 755.
Delirium Tremens, Treatment of, Without Choloral Bromide of Potassium or Opiates, 159.
Dermoids, Price, Joseph, 561.
Destiny of a Ligature used in Ovariotomy After Five-and-a-half Years, 466.
Diabetes Following Extirpation of the Pancreas, 754.
Mellitus, by Means of Pancreatic Juice—Treatment of, 190.
Diagnosis of Cancer of the Pancreas, 228.
Did not Know it was Loaded, 471.
Diet in Obesity, 433.
Different forms of Iritis and their Treatment, Mansfield, Arthur D., 401.
Differentiation of the Typhoid and the Coli Communis Bacilli, 269.
Of Bacillus Coli Communis and Bacillus Typho Abdominalis, 468.
Dilute Nitrohydrochloric Acid, 635.
Diphtheria Treated by Tartaric Acid and Corrosive Sublimate of Mercury Method, Tull, M. Graham, 809.
Diphtheritic Angina, by Chromic Acid—Treatment of, 388.
Dirty Midwifery, 382.
Discriminating Diagnosis Between Cerebral Hemorrhage and Acute Softening, 154.
Dislocations, 363.
Distribution of Bacilli of Diphtheria in the Human Body, 467.
Double Excision of the Knee, 59–221.
Do the Sick ever Sneeze, 948.
Drunkenness with Strychnia—Treatment of, 784.
Drunk or Dying, 524.
Duboisine in Treatment of Hystero-Epileptic Convulsions, 316.

Early Extirpation of Tumors, 154.
Treatment of Congenital Club-foot, Hogan, Samuel Mardis, M. D., 197.
Echinococcus in the Throat, 228.
Eclampsia of Pregnancy, Barnes, I. C., 517.
Treatment of, 435.
Ectopic Gestation, 596.
Enlargement of Cervix during Pregnancy, 898.
Enuresis Diurna, 901.
Epilepsy, 956.

EDITORIAL—

Drainage needed, 971.
Extra Uterine Pregnancy, 666.
Gynecology Among the Insane from Another Point of View, 341.
Home Quarantine, 141.
Innocents Abroad, 263.
Medical Examiner's Bill for Pennsylvania, 548.
Legislation in Georgia, 781.
Schools—Their Management.
"Much Ado About Nothing," 616.
National Quarantine, 100.

Femoral Aneurism—Treatment by Compression, Mol-
Filoy, Rushton, 597.
stula in Ano, Operation, 900.
Five Cases of Vaginal Hysterectomy for Malignant Disease of the Uterus—all recovered, McNutt, W. F. 79.

FORMULÆ—

Abdominal Operation Wounds, Dressing for 869.
Abscesses, 868.
Alcoholism (Chronic), 826-868.
Acute Laryngitis in Children, 855.
Agreeable Salicylic Mixtures, 753.
Allingman's Ointment for Hemorrhoids, 310.
Anal Fissure, 428
Anæmia and Chlorosis, 714.
Antiseptic Dental Cream, 514.
Asthma, 113-714.
Barbers' Itch, 514.
Battery fluid, 869.
Bright's Disease, 869.
Bronchial Asthma, 638.

Burns, Application for 428.
Burns in Children, 311.
Burns of the Eye, 310.
Carbuncle, 753.
Catarrh, Acute Nasal, 113.
Cement for Glass to Glass, 311.
Cementing Iron, 416.
Chancroids, 714.
Chillblains, 753.
Chloral in boils, 753.
C. Chlorodyne, 548.
Cholera Cure, 310.
Cholera Infantum, 753.
Chronic Bronchitis and Emphysema, 795.
Chronic Eczema, 753.
Chronic Rheumatism, 310.
Cleaning Wall Paper, 311.
Coccydnia, 112.
Collodion for Gouty Joints, 714.
Corneide—English Corn Cure, 310.
Constitutional Syphilis, 713.
Counter-irritant in Diseases of the Chest, 714.
Creasote Treatment of Tuberculosis, 113.
Croup, 635.
Cutaneous Diseases, 753.
Cystitis, 635.
Cystitis in Women, 310.
Dentifrices for Mercurial Stomatitis, 635.
Detection of Pus in Urine, 112.
Diabetes, 869.
Diphtheria, 310-427.
Disguising the Taste of Cod-Liver Oil, 714.
Disguise Turpentine, 713.
Dressing for Cuts, Sores, Scalds, etc., 533.
Dry Pleurisy, 752.
Dusting Powder for Children, 428.
Dysentery, Chronic, 869.
Dysentery, Acute, 869.
Dysmenorrhœa, 868.
Earache, 753.
Eczema, (Chronic) 868.
Emulsion, Castor Oil 112.
Enteritis, 869.
Epilepsy, (to Prevent Nocturnal Fits) 868.
Epistaxis, (in Anæmic Cases) 868.
Erysipelas, 634.
Excessive Thirst in Diabetes, 753.
Exophthalmic Goitre, 868.
Expectorant, 428.
Fissures of the Breast, 868.
Fissures of the Nipples, 427.
Fissures of the Tongue, 868.
Frost Bite, 112.
Frosted Feet, 634.
Gastralgia, 541.
General Nervousness and Depression of Spirits, 714
Gonorrhœa, 112-514.
Gonorrhœa in Females, 513.
Habitual Abortion, 714.
Habitual Constipation, 112.
Hard Tooth Soap, 310.
Hiccough, 714-868.
Hooping Cough, 714.
Impetigo Contagiosa, 514.
Inhalation for Whooping Cough, 665.
Ingrowing Toe-nail, 869.
Intestinal Fluxes, 635.
Iodated Water in La Grippe, 428.
Irritable Bladder with Acid Urine, 550.
Irritable Cough, 635.
Laundry Starch Polish, 513.
Leather Bronze, 311.
Liniment for Neuralgia, 112.
Liniment of Subacetate of Lead, 428.
Local Anæsthesia, 635.
Local Psoriasis, 514.
Lumbago, 752.
Mercurial Stomatitis, 869.
Metal to Glass, Cement, 311.
Mucous Patches in the Mouth, 634.
Nervous Cough, 112.
Nervous Debility, 428.
Neuralgia, 753.
Neuralgia in Dysmenorrhæa, 310.
Ointment for Chronic Gonorrhœa, 310.
Ointment for Eczema, 310.
Ointment for Hemorrhoids, 112.
Otorrhœa, 753.
Pain in the Eye, Disease.
Painful Hemorrhoids, 428.
Painless Dilatation of Cervix Uteri, 112.
Paralysis, 752.
Patches on Skin and Mucous Membranes, 752.
Patent Leather Varnish; 311.
Pills of Iodide of Potassium, 948.
Pleurisy, 752.
Pomade for Psoriasis of Scalp, 514-635.
Post-partum Uterine Pains, 539.
Prophylactic for Tonsillitis, 427.
Protracted Croup, 713.
Pruritus Ani, 311.
Pruritus of the Vulva, 868.
Removal of Mother's Marks, 311.
Removing Warts, 112.
Rheumatism, Chronic, 753.
Ringworm, 427.
Round Worms, 515.
Santonin for Children, 311.
Santonin Lozenges, 427.
Scabies and Head Lice, 714.
Scrotal Eczema, 428.
Seborrhea of Scalp, 635.
Secondary Syphilis, 714.
Serous Diarrhœa, 112.
Significance of Subjective Cerebral Symptoms in Middle Ear Inflammation, 116.
Small Hemorrhoids and Pruritus Ani, 112.
Solution for treatment of Chancre, 113.
Soothing Syrup without Opium, 514-868.
Sore Throat, 514.
Substitute for Mothers' Milk, 428.
Sulphur Iodide in Acne, 634.
Swollen Eyes, 753.
Syphilis, 753.
Syphilitic, Oral, Lingual and Pharyngeal Lesions, 427.
Syphilitic Ulcers, 428, 665.
Tape worm, 112.
Tænifuge for Children, 514.
Tertiary Syphilis, 713.
Threatened Abortion, 310.
Thymol and Salicylic Acid against Fœtid Breath, 427.
Tonic Laxative, 635.
Tonsillitis, 310.
Tooth ache, 497.
Transfusion Fluids, 113.
Treatment of Led Colic by Olive Oil, 311.
Trional as a Hypnotic, 228.
Tubercular Abscesses, 634.
Typhoid Fever in Children, 427.
Uremic Vomiting, 714.
Vaginismus, 868.
Varicose Ulcers, 515.
Vesical Injections of Emulsions of Iodoform in Purulent Cystitis, 514.
Vomiting in Pregnancy, 514.
Wash for Pruritus, 428.
Wax from Ear, to remove, 634.
Worm Powders, 427.
Worm Syrup, 427.

Fracture of the Patella, 53-423.
Of Scapula from Muscular Action, Hoover, P. V.. 848.
Of the Thyroid Cartilage, 694.
Frequency of Local Symptoms of Uterine Displacement, 356.

Gall-Stones with Ulceration of the Gall Bladder into the Intestines, Currier, John M., 772.
Gangrene of the Hand Consecutive to Influenza, 227.
Following Fracture of Arm, 60.
Gangrenous Intestine—Treatment of, 865.
Gastro-Enterostomy—New Method, 274.
Intestinal Catarrh in Children, Taylor, J. Madison, 837.
Gastro-Intestinal Atony, 946.
Glanders in the Horse, Clinical Study of, 70.
In Man, 467.
Glycerin Jelly for Mounting, 420.
Gonorrheal Infection—Modes of Extension, 101.
Rheumatism, Vance, A. M., 490.
Gout in Child Eleven Years Old, 115.
Grafting with Pigeon Skin, 788.
Gravid Uterus, by Abdominal Section, removal of, 862.
Growth of Bacteria through the Pasteur-Chamberland Filter, 268.
Gynecology and the General Practitioner, Price, Joseph, 717.
Clinic—Buffalo General Hospital, Man, Mathew D., 323.
Technique, As Carried Out at the Gynecean Hospital, Baldy, J. M. 21.

Hemorrhoids, 24-77.
Hoffkine's Anti-Cholera Vaccines, Preparation of, 467.
Head Injuries with Aural Complications, 43.
Heart Strain, Prophylaxis and Treatment, Stockton, Chas. G., 844.
Heat in local Skin Diseases, 515.
Hemorrhage from Stomach or Bowels, 169.
Hepatic Insufficiency in Mental Disease—Heptic Insanity, 185.
Hernia Ischiatica, 669.
Hip Disease, Treatment of 826.
Hot water Bottles, Disadvantages of, 76.
How to Treat those Overcome with Gas, 316.
Hydatids of the Brain, 189.
Hydrecephalus, 146.
Hydrophobia, 395.
Hypertrophied Floating Spleen; Splenectomy with recovery, 226.
Hypodermic Medication in Syphilis, Wolff, L., 525.

Ichthyol in Gonorrhœa, 874.
Icterus and Acute Atrophy of Liver following Syphilis, 783.
Impacted Cerumen in Auditory Canal, Effects of, Cady, N. W., 444.
Improvised Splints for Fractured Limbs in Cases of Emergency, Simpson, A. O., 534.
Incipient Ischiatic Hernia, 550.
Incisions in the Abdominal Walls, and Ventral Hernia, Treatment of, Ladd, G. D., 14.
Individual Experience in the Treatment of Vesical Calculus, Ashhurst, John Jr., 920.
Indications for Intubation, 754.
Infantile Paralysis, 873.
Infectious Erythemas, 181.
Inflammation; Pus; Positively and Negatively Chemo-Lactic Substances, Cattell, Henry W., 48.
Influence of Massage upon Rapidity of Absorption of Therapeutic Substances, 754.
Inguinal Hernia and Epididymitis, 453.

NO OPENERS

FOR CHAMPAGNE REQUIRED.

By means of a small seal attached to wire, the latter can be broken and easily removed by hand, together with top of cap, on G. H. MUMM & CO.'S Extra Dry.

G. H. Mumm & Co. having bought immense quantities of the choicest growths of the excellent 1884, 1887 and 1889 vintages, the remarkable quality and delicious dryness of their Extra Dry can be relied upon for years to come.

"By chemical analysis the purest and most wholesome champagne."—R. Ogden Doremus, M. D., LL.D.,
Professor of Chemistry, N. Y.

The Demand For

a pleasant and effective liquid laxative has long existed—a laxative that would be entirely safe for physicians to prescribe for patients of all ages—even the very young, the very old, the pregnant woman and the invalid—such a laxative as the physician could sanction for family use because its constituents were known to the profession and the remedy itself had been proven to be prompt and reliable in its action, as well as pleasant to administer and never followed by the slightest debilitation. After a careful study of the means to be employed to produce such

A Perfect Laxative

the California Fig Syrup Company manufactured, from the juice of True Alexandria Senna and an excellent combination of carminative aromatics with pure white sugar, the laxative which is now so well and favorably known under the trade name of "Syrup of Figs." With the exceptional facilities, resulting from long experience and entire devotion to the one purpose of making our product unequalled, this demand for the perfect laxative

is met by Our Method

of extracting the laxative properties of Senna without retaining the griping principle found in all other preparations or combinations of this drug. This method is known only to us, and all efforts to produce cheap imitations or substitutes may result in injury to a physician's reputation, and will give dissatisfaction to the patient; hence, we trust that when physicians recommend or prescribe "Syrup of Figs" (Syr. Fici Cal.) they will not permit any substitution. The name "Syrup of Figs" was given to this laxative, not because in the process

# of Manufacturing

a few figs are used, but to distinguish it from all other laxatives, and the United States Courts have decided that we have the exclusive right to apply this name to a laxative medicine. The dose of

"SYRUP OF FIGS"

as a laxative is one or two teaspoonfuls given preferably before breakfast or at bed time. From one-half to one tablespoonful acts as a purgative, and may be repeated in six hours if necessary.

"Syrup of Figs" is never sold in bulk. It is put up in two sizes to retail at fifty cents and $1.00 per bottle, and the name "Syrup of Figs" as well as the name of the California Fig Syrup Company is printed on the wrappers and labels of every bottle.

ORIGINAL ARTICLES.

A PLEA FOR THE EARLY SURGICAL TREATMENT OF APPENDICITIS.*

A. H. CORDIER, M. D., Kansas City, Mo.†

In selecting this important topic to write on, I am imbued with a desire not only to bring before this society my views, but to elicit a discussion as well, that the deductions may be compared with my observations, experience and understanding of the pathological history of, and the surgical procedure in the treatment of this frequent and dangerous affection. I am of the opinion that my statements will meet with a strong and vigorous opposition from some of the very best practitioners present, whose error (according to my opinion) is a mistake in the interpretation of the exact etiology and pathology of the disease, and not engendered by a desire to oppose progress or to bar the surgical relief of these cases.

All *students* of medicine and surgery have equal opportunities, in so far as the literature on this topic is concerned, to become familiar with its history and progress, and it is true in this case as in many others of a like character, that our utterances are along the line of the teachings of books we have consulted, added to personal experience.

You will find the author or teacher of theory and practice of medicine, holding what he terms a conservative position on all subjects classified as surgical. For instance, the hemorrhoid has an ointment applied, the osteomyelitic tibia has a liniment and hot fomentations for weeks, while the disease with rapid strides gains ground and undermines the general physical condition of the patient.

From a surgical standpoint, we have men who are so desirous of tabulating a vast number of surgical cases, that the patient has only to diagnose his hemorrhoid, her cystic (?) ovary, or the presence of a phantom tumor, to press the button and the surgeon will do the rest. While these declarations are a little overdrawn, both from a medical and surgical view, yet it is only by a difference in degree and not in kind that they can be called exaggerations. We have a medium in all things, both medical and surgical, appendicitis and a few other rapidly death producing and recurring processes, excepted.

The location and tendency of a disease should place the radical or conservative stamp on the procedure for the relief or cure of the same. A hemorrhage from a small meningeal vessel may cause death speedily, if not immediately controlled by rational surgical procedure. A bleeding from the nose would be passed by as a trivial affair, requiring no farther treatment than that of conservatism—let it alone and it will stop of itself.

I imagine that my position is now understood and that some of my friends present are "laying" for me.

I have heard the subject of appendicitis discussed by the most learned body of medical and surgical gentlemen ever assembled in this country—where such men as Bryant and McCormack, of London,

† Read before Kansas City District Medical Society, Dec. 8, 1892.

* Member of American Medical Association, Member of American Association Obstetrician, Corresponding Member of Philadelphia Obstetrical Society, etc., etc.

Agnew, Price, Keen, Morton and Ashurst, discussed the subject from a surgical standpoint, while Da Costa, Pepper and others, spoke from the medical side. While these great surgeons with a vast experience, as a unit, endorsed early operative interference, the equally celebrated medical gentlemen advised delays and tinkering, but all agreed that the disease was one attended with much danger, with a tendency to return, and that many of the cases required operative procedure for its relief or cure.

I shall dwell upon the anatomy of this part of our make up, only to call attention to the fact that the cæcum and the appendix have a peritoneal covering. At the same time, I want to disabuse your minds (if any so believing are present) of the possibility of doing an operation for appendicitis *extra peritoneally*.

The appendix has only a slight vermicular movement to expel or dislodge any substance once in its cavity. Post-mortem examinations and surgical operations have demonstrated that with very rare exceptions (traumatic, typhoid, tubercular, neoplastic) inflammations occurring about the head of the colon are, primarily, of appendicular origin, and that the exciting cause was some foreign body lodged in this functionless and dangerous rudimentary appendage. It is the experience of surgeons that the disease is of cæcal origin once only, in every one-hundred and fifty cases, so we can safely eliminate from the diagnosis or consideration of the pathology these exceptions by their extreme infrequency and by the fact that *they* demand the same surgical procedure up to the point of establishing a positive diagnosis.

A few years ago "*inflammation of the bowels,*" so-called, was of frequent occurrence, and "*idiopathic peritonitis*" was not rare, the causes of both being a mystery unexplained up to the beginning of the true history of appendicitis and salpingitis. Since the pathology of these two intra-peritoneal diseases has been correctly understood "pelvic cellulitis" and "inflammation of the bowels" are terms rapidly disappearing from our medical and surgical nomenclature.

A body (grape, orange or cherry seed) having once entered the appendix, let us see what takes place. The foreign body is there to stay, unless by accident it escapes, as this tube has not the power to expel it. A cherry-stone in close confinement in the narrow prison, surrounded by moisture and warmth soon settles down to business, and, as a result of its presence and pressure, an ulcer forms beneath it. As this approaches the serous covering, the ever-present pathogenic bacteria find an avenue of escape and swarm toward the peritoneum. The peritoneum with its endothelial covering, and the phagocytes at once begin an active warfare with the intruders (Metschnikoff). Breastworks are built up from the dead of the conflict, and the war goes on or, for the time, peace is declared, according to which force is the stronger.

Now, while this is taking place within the iliac fossa, the unfortunate victim is having a temperature from 96° F. to 105° F. according to the extent of peritonitis, amount of septic absorption, or intensity of the shock following a perforation. The breastwork is nothing more or less than an effort on the part of nature to wall-off and limit the destructive process that is threatening the general peritoneal cavity.

The patient has a constipated bowel from two causes, one from a drying-up or a checking of the intestinal-juices, and want of peristalsis—too frequently as a result of large and repeated doses of opium for the relief of the pain. He will have more or less tenderness in this locality, diffused or circumscribed according to the extent of the inflammatory processes within. McBurney's point is painful on deep pressure in most cases, the exceptions being where the appendix is not in its usual location. If the disease is very far advanced (I mean if the inflammatory deposits are at all extensive), you will be enabled to map out a well-marked dullness.

Your patient will go from bad to worse in this stage of the disease, or, his fever may subside, his pain *in part disappear* (tenderness on deep pressure will remain), appetite return, bowels become regular and he may be, so far as his general appearance goes, in good health.

Now let me picture to you his local condition: Nature has for the time being built up a barrier, that holds the disease in check, but this fortification, you must remember, has within its walls the original source of the trouble,—it may be a fæcal concretion, a grape, or an orange seed.

He is in danger of a relapse at any time; and each time the disease is started up anew, there is added fresh complications, the danger is increased and the likelihood of your surgery being successful diminished. His next attack may prove fatal.

The diagnosis and the history of this disease is so thoroughly understood by all that it would be useless to dwell further on this point.

In the matter of pathology and treatment, I am sorry to say, there is a want of unanimity in the profession that too often leads to dangerous delay in resorting to surgical procedures for the speedy relief of this condition.

The medical treatment I will sum up in a few words. *Of much import is the minimum of time in following out the medical course.* Salines, in good full doses, are indicated above all other remedies, as the watery action produced by the salts is a good preparation for the surgery that must follow. *All opium should* be *avoided,* as it masks the symptoms and places the patient in a bad condition for an abdominal operation. Codeia, etc., etc., may be tried. Blistering does no good, besides leaving an infected surface to cut through. Indeed any case with symptoms so severe as to require a blister is grave enough to demand coeliotomy. Hot applications add to the comfort of the patient but produce an œdematous condition of the abdominal walls and do not add to the chances of recovery. This œdema may mislead the surgeon as it gives a sense of fluctuation on examination. Large warm water enemata, to which is added a teaspoonful of turpentine, will empty the colon of feces and gas, and thereby make the patient more comfortable.

The technique of the surgical procedure must of necessity be such as to fulfill the indications in individual cases. In one case the appendix will have to be ligated and removed; in another the appendix may be found lying loose in an abscess cavity, having sloughed at its junction with the cæcum. Again you may find the appendix bound up in a mass of adhesions—the condition often found in delayed or relapsing cases.

No major operation in surgery, where it is performed early, has a lower death rate; and no capital surgical procedure has a higher mortality following it than this, if postponed beyond the safe period for operation. I say following the operation because the deaths following the operation are due, in most instances, to the fact that the patient is dying at the time the operation is performed. You cannot rescue a patient suffering with a diffused septic peritonitis, with fæcal matter or other septic material (pus) all over the omentum, mesentery and diaphragm.

Gentlemen you must operate early on these cases and your results will be attended with an *almost nil* mortality. I believe the position taken by Prof. Keen is a correct one, when he declares, that the physician and the surgeon should see the case together right along from the day the symptoms point to an attack of appendicitis.

If your patient does not improve in a few days (say three at farthest) under salines, restricted diet, etc., etc., I would advise resort to operation. Some cases die within a shorter period following the first manifested symptoms of the disease. Operate at once. *Do not delay an hour.* If the bowels do not move from the effects of the salines and the symptoms persist, even though mild, operate at once. A constipated bowel is always a bad symptom in this disease even though other symptoms point to a mild attack. If in relapsing cases (old abscesses) there is an indication of septic absorption, we have special reason for immediate operation. Cases should be operated on before a septic condition is developed. We should operate in children as soon as possible, for the disease makes quicker inroads in the young than in the adult.

I desire to lay stress upon the fact that the heighth of the temperature and the severity of the pain in these cases cannot be used as guides to point out the indications for or against an operation. The temperature may be, and in fact often is, subnormal, especially in the acute perforative cases. The pain is often masked by large doses of opium.

If you decide to wait at the solicitation of the patient or of the family, watch closely for the advent of alarming symptoms and insist on an operation the moment such are observed. I do not advise procrastination but we must consult the wishes of the patient and abide by his decision, even against our own better judgment.

The surgeon who undertakes abdominal work should be familiar with all the complications liable to be met with in this locality, and quick in his dealings with the same. The disease may have produced such wide-spread death of the intestines that an extensive resection and anastomosis may be necessary.

Unless the surgeon has by constant study, experimental work and operative experience made himself acquainted with all these details he will find his inventive resources taxed to the uttermost to meet unlooked for complications.

The diagnosis of inflammatory disease at the head of the colon by the painstaking general practitioner, in the great majority of instances, will be found to be correct and the only point of disagreement with the surgeon will be the pathology and, occasionally, the propriety of surgical treatment. This disagreement will persist so long as there exists a division of opinion on the point of origin of the disease, that is—did the disease originate in the appendix and extend to the cæcal region, or is it primarily of cæcal origin? Gentleman, I assure you, it will be safe to say the appendix every time.

I briefly report a few cases that it has been my lot to observe, either in consulttation or as attending physician. I desire to preface the reports by the confession, that my management of some of the earlier cases now meets with my strongest condemnation, and as I recall these facts it is with a feeling almost akin to that of criminal negligence or unpardonable surgical timidity.

Case I. Miss B., age 20; German. This young lady was taken sick Feb. 28, 1887. Had a severe chill. Had a pain in right iliac fossa radiating into the right lumbar region. This pain is paroxysmal in character but she has pain all the time (this is a diagnostic symptom in excluding colic and other non-inflammatory diseases.) Has been vomiting a greenish, sour-smelling material, is sweating profusely (a bad symptom,) temperature 100, pulse 120. Bowels have not acted since 25th. (a constipated bowel is also an unfavorable symptom.) Pain on pressure over cæcum. Dullness on percussion (this is the fifth day since she first complained, and the first time I saw the case.) Has had infusion of senna with no results. I suggested an operation if *improvement did not begin soon*, (I should have said *operate at once*) at same time prescribed large doses of morphine. (This I now recognize as an agent to mask the symptoms and result in bringing about a false feeling of security in the mind of the patient and the family, and even to put a staying hand on the better judgement of the surgeon and thus cause him to delay intelligent surgery which is too often responsible for the loss of valuable lives.) At my next visit I found her as she expressed it "feeling better." March 8, or ten days since the beginning of the attack, I find her much worse. On the night of March 10, she was taken with a most unbearable pain in the region of appendix, followed by profound shock (perforation of abscess wall and escape of pus into general peritoneal cavity). She died a few hours later.

This young lady to-day, gentlemen, would be living in so far as this attack was concerned had she received the benefit of good, timely surgery. I have since operated early on very similar cases and saved them.

Case II. April 5, 1889. I saw this case in consultation. Mrs. L., aged thirty-four; mother. Three days before I saw this lady, she was taken with a chill (she had been feeling badly for several days), the temperature soon ran up to 105° F. (due to rapid absorption of septic material). She has great pain in cæcal region, tenderness *localized*. Bowels acted from effects of a dose of Epsom salts administered the day before. This was good treatment. An obscure sense of deep fluctuation is discoverable. Peculiar facial expression, seen in patients suffering with peritonitis or marked shock. I advised an operation at once, but my proposition met with a square and obstinate opposition from the uncle who had charge of the case. This was the last time I saw the case. Fifteen hours before her death she developed symptoms indicative of perforation, the shock following lasted up to her death. No one, I trust, will question the propriety of urging early operations in like cases. Any case, even the mildest, may quickly assume this dangerous character.

Case III. This case was reported soon after its occurrence, as a case illustrating the position taken by some writers, even at this date (I was of same opinion at that time), that fæcal impaction is a frequent cause of inflammatory processes in this

locality. The post-mortem a few months later revealed a cancer of the cæcum.

Mrs. H., age 30, mother. I saw this case in consultation. For some time she had noticed an enlargement in region of cæcum, movable, painless and doughy (?) to touch. Has had colic pains for a month, constipation alternating with diarrhœa. Temperature 108° F., pulse 124. Some pain in abdomen. I diagnosed the case as one of fæcal impaction of cæcum, with a mild attack of perityphlitis. I saw her a week later and found her "about the same." Entered in my record book at this time, "This is one of the cases of perityphlitis in which a delay of surgical procedure is not only justified but desirable."

Case IV. Willie K., age 20, male. November 20, 1892. I was called to see this young man in consultation with Dr. Smolt, of Nickerson, Kansas. The doctor had diagnosed the case correctly and insisted on early operation, but owing to the the fact that the patient's parents lived in Buffalo, N. Y., some valuable time was lost in getting the father's consent. At the time I operated, the temperature was 96.5° F., (please note this fact, as a high temperature does not necessarily accompany the worst form of the disease). His pulse was 55. He was hiccoughing and vomiting frequently, countenance pinched, cold, clammy perspiration all over the body. In fact, his condition was one, the outlook of which was certainly very unfavorable. Without an operation death was near at hand.

The operation was quickly performed, only twenty minutes of *anæsthesia.* An inflammatory mass as large as the closed hand was found surrounding a diseased and perforated appendix. A cherry stone was lying loose in the abscess cavity. A perforation at the junction of the appendix to the cæcum was found and left open; no attempt to remove the appendix was made. The abscess cavity was carefully irrigated and cleansed with peroxide of hydrogen, a rubber drainage tube introduced surrounded with iodoform gauze; a large opening was left through which the contents of abscess might escape.

While this operation was not an ideal one in its completeness, it was certainly good surgery as the results in the case show. The young man to-day is up and about his room. The appendix will probably atrophy, the inflammatory mass will in a great measure, be absorbed, and that locality will in all probility cease to give him further trouble. Should it threaten him with another attack, an *early* operation, before he is in the very grasp of death, shouid be performed and the mass broken up or the appendix removed. I do not think this will be necessary.

I submit to you for discussion, the following deductions:

1st. This is a disease of frequent occurrence and one attended with much danger.

2d. The disease primarily located in the appendix, may exist for months or years in a semi-latent state before well-marked or alarming symptoms develop.

3d. That inflammatory diseases located about the head of the colon, in the great majority of cases, owe their origin to a diseased, ulcerated or perforated appendix.

4th. The percentage of death from this disease will continue to diminish in proportion to the correct understanding of the pathology and the recognition of the necessity of early surgical relief being resorted to.

5th. All recurring and all well-marked cases of appendicitis should be operated on at once. This applies with special force to patients who have had a number of attacks and are contemplating a journey to localities where skilled surgical aid can not be quickly obtained.

When the soft tissues are crushed and the surgeon is in doubt where to operate, and waits for the line of demarkation to form, poultices should not be used, for they sodden and thus weaken the tissues. Hot water should be applied every hour for five to ten minutes at a time, and during the interval the part should be wrapped in hot dry cotton.

The physician may give advice on tobacco in a general way, but he will find very few patrons who will tolerate his presence professionally if he advises them to drink less coffee, to smoke fewer cigars, to chew less tobacco or to take less whisky. They think they know what is good for them better than the men who make a life-study of the causes of disease, and know why and how they undermine health and life.—*Ex.*

SOME SUCCESSES AND FAILURES WITH ELECTRICITY IN GYNECOLOGY.

A. LAPTHORN SMITH, B. A., M. D., M. R. C. S., England.

My experience with electricity in gynecology has been limited to :

1. Positive Galvano-Punctures.
2. Negative Galvano-Punctures.
3. Positive Intra-uterine Applications of Galvanism.
4. Vagino-abdominal Applications of Galvanism.
5. Intra-uterine Bipolar Fine-wire Faradism.
6. Vaginal Bipolar Fine-wire Faradism.
7. Intra-uterine Coarse-wire Faradism.
8. Vaginal Bipolar Coarse-wire Faradism.
9. Vagino-abdominal Coarse-wire Faradism.

Positive Galvano-Punctures.—I have had one very marked success with positive galvano-puncture in a case of enormous uterine polypus, in a patient who was so exhausted with hemorrhage that no surgeon would dare to give her an anaesthetic in order to remove the polypus, which was the size of a seven months' foetal head, and nearly filled the pelvis. Half a dozen positive galvano-punctures were made into the tumor as a palliative measure, with the result that the hemorrhage and profuse watery discharge were stopped, and the patient improved so much in health that she would not entertain the proposal to remove the tumor, apparently suffering no inconvenience from it. I followed her up for about a year, since which I have lost track of her. Although I employed currents of 150m., the treatment was absolutely devoid of pain.

On the whole I am opposed to galvano-puncture, having lost one case through an error of diagnosis and neglect of strict antiseptic precautions ; and having, in another, caused a good deal of suffering without proportionate results. My chief objection to it, however, is that it almost surely causes adhesion, which in case of the necessity ever arising for removal of the uterus, would greatly increase the difficulties of the operation. A minor, but still important objection to punctures is that they frighten the patient away from continuing the treatment.

I have to record one complete failure with *negative galvano-punctures* to relieve the pain of an impacted non-bleeding fibroid. The death above referred to is the only fatal or even dangerous accident I have had since I first began the use of galvanism.

With *positive intra-uterine* applications, on the contary, my success has been almost invariable. I have employed them in rapidly-growing bleeding fibroids, in subinvolution, in fungous endometritis, and in menorrhagia from other causes, the disease having been arrested in about 90 per cent. of the cases. Success has been due to attention to the following points :

Correct diagnosis ; the introduction of a solid or flexible sound the whole depth of the uterus ; the employment of a sufficient current strength to furnish at least 25 milliamperes to each square centimetre of surface of the sound, and the rigorous following out of the aseptic and all the minor details of the method as laid down by Apostoli One of my failures (Miss B.) to arrest hemorrhage with positive intra-uterine application of galvanism was due to the eating into a small uterine sinus with the end of the electrode, which, at that time, I was not in the habit of taking the precaution of insulating with a little wax.

This case would have been a complete success had it not been for this accident, but owing to the slight hemorrhage lasting however, two weeks I was led to class it as a failure and the uterus was removed. The patient made a good recovery and is now enjoying good health.

It is interesting to note that, although she received over 50 strong applications with the clay electrode on the abdomen, there was not found the slightest sign of an adhesion anywhere, except at a small spot at the back of the uterus where the latter had been rubbing on the brim of the pelvis.

Another failure, Miss S., was due to the condition of the appendages which prevented me from giving adequate doses. By the aid of a little anæsthetic occasionally, I was able to give her 100 applications, lasting each from seven to ten minutes and of an average strength of 100 milliamperes. The tumor was reduced in size one-fourth, the hæmorrhage was re-

duced fully three-fourths, and the patient regained her color. But her home being a thousand miles away, and as she feared that the hæmorrhage might recur when she would not be able to recur for treatment, she urged me to perform hysterectomy, which I told her was the only absolutely certain treatment that would prevent hæmorrhage returning. At the operation there was not a sign of an adhesion anywhere after 100 applications of galvanism, some of the doses going as high as 175 milliamperes. She made a rapid recovery, and is now in excellent health, performing her duties as principal of a high school where there are 600 girls. So far from the treatment with electricity making the operation more difficult and complicating it with adhesions, I felt convinced that it had placed her in a much better position for undergoing it. I certainly should have dreaded undertaking the operation while she was in the exsanguinated condition which she presented when she first came under my care. If she had resided in this city, or anywhere where she could have reached me and received further treatment in case of a return of the bleeding, she would not have required to have undergone the operation at all.

In another case of failure with the positive pole (Miss S.,) in the uterus, the patient had been sent to me with a diagnosis of fibroid, which had been made and confirmed by several leading surgeons. The tumor at first diminished in size, and the patient's general health was much improved, but after a time it suddenly began to grow again, when I sent her to the hospital for operation, at which I was present. The tumor proved to be a sarcoma of the ovary into a depression in which the uterus was imbedded, rendering it difficult to differentiate the one from the other by digital examination.

A brilliant success, however, was a Mrs. P., who had bled so much that, as a last resort, a leading gynæcologist in the city had packed her with ice. I kept her tamponed with alum tampons for a few days until I could improve her enough to be carried to my office. The introduction of a soft bougie to measure the depth of the uterus caused the blood to pour out on to the floor of my office before I had time to catch it. Her skin was waxy and absolutely colorless. After twenty or twenty-five applications her periods became perfectly normal, and have remained so for several years. I took the trouble to hunt her up a few months ago to present her to the medical society, and found that she had been in perfect health ever since, suffering no inconvenience whatever from the tumor which had been reduced fully a third. This woman would surely have died whether she had been operated on or left alone; in fact, no one would have dared to operate on her in the almost pulseless condition in which I first saw her.

Another brilliant success was Mrs. S., an artist by profession, who had almost become a hopeless invalid, but, who after only fifteen applications of galvanism was restored to almost perfect health, and has not lost a day from her work since. The tumor was reduced a third in size, and she suffered no inconvenience from it whatever. It is now three years since the last application, and she has had no relapse. Another successful result from the positive pole in the uterus was Miss A., chambermaid in the Windsor Hotel, who was about to abandon her occupation when she came under my care, but after fifteen applications was able to resume her work, and has been well ever since—now two years ago.

Mrs. X., wife of a physician in this city, used to bleed so severely that she had to pass a week out of every month in bed, with her feet raised and her head low, and even then she would faint repeatedly; after ten applications was so much improved that she was no longer obliged to remain in bed at all. I subsequently curetted the uterus and repaired the lacerated cervix and perineum, and now she is enjoying very fair health.

Miss A., was sent to me from Scranton, Penn. She was an expert stenographer, but was unable to keep a situation because for ten days in every month she had to remain in bed. If she attempted to remain up, large clots would come away, so that she would have to stand in the office over a newspaper and allow them to fall on it, besides which she would saturate a dozen napkins a day with the serum. After 100 applications her periods came down to three days, and she is now married.

Mrs. P., from a distant city had to be carried into my office, but was able to walk a distance of two miles after having

received ten applications. She received in all 50 applications, the last one three years ago, she has remained well ever since.

One of my most recent successes is Mrs. F., of this city, who was affected with severe hæmorrhages, and who after about 20 applications was relieved of all her symptoms. There has not been any return of the hæmorrhage since leaving off the treatment three months ago.

Two cases which were sent to me as bleeding fibroids were not cured by electricity, as they subsequently proved to be, one sarcoma, and the other epithelioma of the uterus.

In both, however, the hæmorrhage was arrested, although one has since died and the other will soon die.

All the cases so far mentioned, with the exception of the last two of cancer, were cases of bleeding fibroid tumors of the uterus and they were all in women under 40 years of age. They were all treated with positive intra-uterine applications. In another case of a woman, Mrs. N., who had been bleeding steadily for a year, and who had also a bad lacerated cervix, there seemed no doubt about the cancerous nature of the disease. Hæmorrhage was permanently arrested by only half a dozen applications of the positive pole. My success in this case led me to entertain the hope that we had at hand a cure for uterine cancer, but in another case far advanced the treatment proved an utter failure. If it is to be of any use the cases must be seen early.

Besides these 15 cases I have treated about 45 cases with the positive intra-uterine pole, for other conditions, principally for fungous endometritis, endometritis with hæmorrhage at the periods, but also in cases of subinvolution. Of these 45 cases I can only recollect two failures to arrest the hæmorrhage. In every case the depth of the uterus was diminished. There has been no failure to produce this result. In one case the effect was especially gratifying. An old lady with her womb lacerated, large and heavy, hanging between her legs, to whom I administered about half a dozen positive applications followed by coarse wire faradism. The womb became reduced to its normal weight so that a little toning up of the supports rendered them able to keep the organ within her body, where it remained till her death, two years later, from apoplexy.

The following cases were treated with *negative intra-uterine galvanism*, and gave me some of my most brilliant results.

Miss W., who had suffered agony for several years from pressure on the urethra and rectum, and was obliged in consequence to abandon her occupation as cook in a gentlemen's family, was completely cured four years ago by about 20 applications, so that she was able to start and carry on sucessfully a large boarding house for which she now does both the cooking and the catering. The last time I examined her the tumor could not be felt.

Mrs. D., from a town near here, had suffered for 8 years from pressure symptoms, but not from bleeding, from a large intestinal fibroid. Her health had been completely broken down by the large quantities of morphine which her suffering necessitated. One hundred applications cured her, so that two years afterwards her physicians wrote me that the tumor had entirely disappeared. Although it is now over four years since her treatment, menstruation is regular and painless, and she continues in excellent health.

Miss McP.,· suffered so much from pressure symptoms that she was obliged to give up her situation as cook. Her tumor was growing rapidly. After about 20 applications the growth was arrested, and she felt so well that she entered the writer's service, where she has ever since, now five years, performed her duties without interruption.

Mrs. D., from Holyoke, had a large submucous fibroid which was growing rapidly. After the first application there was no increase, while after the tenth there was so much diminution in the size of her waist that she decided that she was cured, and started for home. She was taken with severe expulsive pains on the train, and soon after reaching home she gave birth to a broken down fibroid about the size of a seven months child's head, since which she has enjoyed good health.

In half a dozen other cases of fibroid the pains and pressure symptoms were fairly well relieved by negative applications.

In the treatment of dysmenorrhœa I have had some very gratifying results, so that I can say that I know of no treatment except removal of the appendages which can offer such good prospects of relief. Since

reporting nine cases of dysmenorrhoea cured by negative galvanism, I have added half a dozen more to the list, while only one has utterly failed to be relieved, and one relapsed until she received two more applications, since which she has remained well.

With sacro-abdominal application of galvanism I have not had any marked success, although I have only given it a limited trial.

With *vagino-abdominal applications,* I have seen the tender, enlarged and prolapsed ovaries become lighter, painless and to disappear from Douglas' cul de sac. I have also on three occasions seen the uterus, which was previously bound down and retroverted, become movable. While I can hardly believe that organized bands of adhesions can be dissolved, or, in the words of the electro-therapeutical poet, "Melt away like snow before the summer sun," I can believe that such a powerful alterative may so improve the circulation in the lymphatics that soft or liquid exudations may be reabsorbed.

With *bipolar fine-wire faradism,* I have treated at least 50 cases, principally of inter-menstrual pain, due to neuralgia of the uterus and ovaries, and of varicocele of the pampiniform plexus. I have sometimes used it in some of the above mentioned cases of fibroid in order to establish tolerance for the galvanic current. For any kind of pain in the pelvis, in which no organic disease of the uterus or appendages could be felt by careful bimanual examination, I have found bipolar faradism invaluable.

Where it has failed to relieve, subsequent operation has revealed undiagnosed pus in the pelvis, for which, of course, there is only one treatment, and that is evacuation. I have sometimes used it in the uterus, but most often in the vagina, which seems to be much safer and almost as effectual.

With *coarse-wire faradism* I have also had very satisfactory results in cases of retroflexion due to atony of the uterus and also in cases of prolapsus. In one case of procidentia of a very advanced type it failed to keep the uterus up ; but in at least a dozen other cases of more moderate degree in which the uterus was not much enlarged, a few applications of coarse wire faradism toned up the relaxed vagina and perineal muscles, especially the levator, and that the women have declared that they were greatly relieved, and some of them have even returned each succeeding summer during the hot weather to have their pelvic contents toned up.

The subinvoluted uterus, like the uterus at the end of pregnancy, responds very readily to the faradic stimulus, and any one who has employed coarse-wire bipolar faradism in the vagina cannot have failed to notice how the electrode is grasped by the sphincter of the vulva and drawn up by the levator ani.

Vagino-abdominal coarse-wire faradism I have used several times with the view of shortening the round ligaments, as it has been demonstrated that the freshly removed round muscle will, when stimulated by the faradic current, lift a weight of a pound and a half off the table. But the result was too slow in coming, so I was tempted to perform Alexander's operation instead.

As this paper is entitled some "successes and failures with electricity in gynecology," I have not given a very detailed account of every case. It is rather a general stock-taking after nearly five years experience with it.

As far as I know the harm I have done with it has been limited to one death and two miscarriages all due to mistakes in diagnosis. I believe that I have saved at least 20 women from operation and three or four from death, while I am absolutely positive, certain electrophobists to the contrary notwithstanding, that in those whom I treated with electricity, but whom I did not save from operation, the operation was in no way rendered more difficult thereby, but in all probability their chances were improved, all of them having made easy recoveries.

I think it is unjust and unfair for my friend, Dr. Joseph Price, and others to lay all the blame of adhesion on electricity when they know as well as I do that these complications are met with in cases which have never been touched with electricity, while on the contrary they know that cases which have been treated for a year with electricity were found at the operation to be absolutely free from adhesions.

A hot infusion of capsicum is recommended for hiccough.

CLINICAL LECTURES.

CARCINOMA UTERI.*

E. E. MONTGOMERY, M. D., PHILADELPHIA.†

Ladies and Gentlemen:—I show you a patient thirty-five years of age, native of Russia, who, unable to speak English, affords us a very imperfect history. She had none of the diseases of childhood, and enjoyed excellent health until after the birth of her last child; married at eighteen, has had eight children; five died in infancy, three living and healthy. All her labors were normal and she has had no miscarriages.

After the birth of the last child, menstrual periods occurred at intervals of two weeks; flow was profuse, no pelvic pain. Nine weeks ago she was so weak as to be unable to go about. She at present complains of intense pain along the thighs and of headache. The other symptoms are gastric; burning sensations in the stomach and along the œsophagus; flatulence, vomiting, bowels obstinately constipated, urine negative. She has a profuse watery discharge from the vagina, greenish in color, and with an exceedingly offensive odor.

Now the history of this patient, her age—thirty-five years—married at eighteen years, suffering for three years from profuse menorrhagia, and profuse hemorrhage occurring as often as every two weeks, severe pain and profuse offensive discharge. These symptoms would at once cause you to suspect some serious diseases of the genital tract. In examining the patient we find the vagina filled up by a mass, projecting into it from the right side, and anteriorly a large mass which on its lateral surface is smooth in outline; as we pass toward the central part it is quite friable. This mass is found to fill up the pelvis, pressing upon the surrounding organs and is so friable if we make much pressure against it, it would break down and hemorrhage would result. We have here a degeneration which is without question malignant.

Diseases of this kind are much more likely to be found in women of an older age It occurs more particularly near the climacteric, or immediately following it. It is a condition which is found with greater frequency in women, who like this one, have borne a number of children. While it occurs with greater frequency between the ages of forty or fifty, its presence should not be overlooked when symptoms such as these present themselves in young women, as I have seen a patient in this house dying with cancer who was but twenty years old. As we have already said, it occurs more frequently in women who have borne a number of children The cervix is the usual seat of the disease. We can readily understand why the woman who has borne a number of children and has consequently suffered lesions during parturition, which have been but partially repaired by the processes of Nature, should be more likely to suffer from such degenerations. Tissue of low vitality, subject as it is to frequent irritation, is likely to take on malignant change.

Because the disease, however, occurs so frequently in women who have given birth to children, and is in the majority of cases found in the cervix, it should not be forgotten that it may occur in women who have never been pregnant, and is also found in the body of the uterus. I had a patient in this house, about fifty years of age, suffering from hemorrhage, who had an unruptured hymen and yet the entire cervix was destroyed by an epithelioma. In about two per cent. of the cases the disease is found in the body of the uterus. The disease begins in the glandular tissue of the organ, and subsequently invades by processes of infiltration the subjacent muscular structure, until the entire organ may be involved.

The symptoms of the disease will depend much upon its form. Thus, in the epithelioma we may have extensive cell proliferation, formation of large masses, oftentimes cauliflower in character, which may fill up the entire vagina, are exceedingly friable, breaking down under the touch, and bleed from the slightest irritation. In these cases pain is not usually a marked symptom. Some patients indeed, go through the entire progress of the disease without suffering from pain. In the variety known as scirrhus, there is a firm infiltration of the

* Delivered at the Phila Hospital, November 5th, 1892.

† Professor of Gynæcology, Jefferson Medical College; Obstetrician to Philadelphia Hospital; Gynælogist to St. Joseph's Hospital.

walls of the uterns, giving rise to a hard, dense mass. In these cases the pain is intense, due without question to the pressure upon the involved nerves; one of the earliest symptoms is hemorrhage. This may be an increase of menstrual flow, a slight bloody discharge in the intervals, or a return of bloody flow after the establishment of the menopause. The occurrence of hæmorrhage should always be considered a suspicious symptom, indicating the necessity of careful examination of the genital tract to determine its cause. While hemorrhage at the climacteric, or following it, is usually regarded as a suspicious symptom of malignant disease, it does not always necessarily follow that such disease is present. I remember some years ago being called in consultation to see a patient forty-five years of age, who had had two children, was suffering from irregular menstruation with severe pain. Examination disclosed the cervix apparently normal; the mere introduction, however, of the sound into the uterus was followed by profuse flow. Her age, association of pain, and hemorrhage, led me to believe that she was suffering from malignant disease of the mucous membrane of the body of the organ. The removal of the uterus was advised and was subsequently done by the vaginal method. Upon opening the organ I was much discomforted to find that the hemorrhage had resulted from a submucous fibroid the size of a hickory nut in the wall of the fundus. For this reason I say that such patients should be subjected to a very careful examination to determine certainly that the disease is not malignant. Hemorrhage may also result from a papillary growth of the uterine mucous membrane, which, while it is not malignant, may possibly be a forerunner. These patients usually, however, are cured by careful curetting of the cavity.

Another constant or early symptom of malignant disease is offensive discharge. This, not unfrequently, is thin and watery, giving an odor of decaying flesh. It is very noticeable to the patient and those who may come in close proximity to her. The discharge arises as a result of a breaking down of the infiltration, and taken together with hæmorrhage and with pain, is a very reliable symptom. It should not be forgotten, however, that the patient may have an abortion and retained placenta, or portions of the decidua which may disintegrate and undergo putrid decomposition, causing an offensive odor. Then, too, fibroids of the uterus may have lost their vitality, become sensibly separated from the wall of the organ to such a degree as to slough, giving rise to thin, watery discharge, to an odor of putrid flesh, so that even this symptom requires careful physical examination before it can be considered as a pathognomonic sign.

In enumerating the symptoms, then, of cancer, we have: hæmorrhage, rarely absent; offensive discharge, usually present; pain of a radiating character, sharp, lacinating, sometimes felt in the sacral and lumbar regions, extending down the thighs, not necessarily a constant symptom.

After the disease has continued for a length of time, as a result of hæmorrhage, or the loss of rest, and pain, with the drain from the discharge and the absorption of septic material, the patient becomes anæmic, pale, emaciated, presents a sallow, cachectic appearance, the result of septic absorption. This cachectic appearance, of course, may be associated with other conditions, as loss of blood, from presence of fibroid, severe hæmorrhage following an abortion, with retention of decomposed clots or placenta and the absorption resulting from it. As the disease pursues an uninterrupted course, we find it extending from the structures first involved to those in the immediate proximity, involving one or the other lip of the uterus, extending into the vagina, infiltrating its walls and subsequently in processes of ulceration, opening either into the bladder or rectum, or in some cases into both, producing thus a cloaca into which urine, feces, and discharges mix, giving rise to the most offensive odor that could be possibly imagined.

As the disease progresses it is rare to find the peritoneal cavity opened by it, for the reason that Nature interposes a barrier of lymph, the parts become thickened and the cavity thus shut off.

In a patient with the disease so extensive as the one we have before us, we will ask, "What shall be done?" So far as any attempt at radical cure, nothing. The disease has extended beyond the uterus into the pelvic structures to such a degree that no operation could accomplish its entire removal. Any operation consequently is worse than useless. It is not right to subject the pa-

tient to a dangerous operation which affords no hope of radical cure. In this patient, the use of the curette, cutting away the diseased tissue, will decrease for a time the unpleasant odor, might possibly arrest hæmorrhage, but upon the denuded surface thus formed, the cancer cells would implant themselves, infiltration would be more rapid and the death of the patient occur sooner than if we did nothing. The use of the cautery or caustics, after curetting in some cases, is attended with very beneficial result, patients recovering for a time, appearing in fairly good health until the disease again has extensively developed.

There are other cases, however, which may appear fully as promising at the time of operation, in which the method of treatment seems, if anything, to hasten the progress of the disease. Where the disease involves the anterior lip, and extends from it to the vaginal wall, we not unfrequently find the infiltration pressing upon the orifices of ureters, giving rise to difficulty in passage of urine. Its accumulation consequently in the kidneys causes the development of an uræmic condition which hastens the fatal termination, and during which, as a result of its retention in the blood, the patient is much less cognizant of pain. In this respect it is a rather satisfactory form of progress.

In this patient nothing remains but to make her as comfortable as can possibly be done during the remainder of her life. In order to do this we will direct that anodynes shall be given, to give her rest at night and ease her pain. In giving anodynes, it is well enough not to begin with opium or morphine, but rather to save these agents for a later period, giving in their place a palliative, as hyoscyamus, chloral, and the less active anodynes, not to save the patient from the formation of the opium habit, but rather to economize the effects of that drug, so that when she reaches a period or stage of the disease in which it is needed, we may have it still to resort to.

Locally, patients should be given vaginal enemas, bichloride or acid sublimate solutions, solutions of sulphurous acid or carbolic acid, or what is more effective probably than any, a solution of thymol, the latter agent for the purpose of removing the offensive odor. The patient should be kept in a room that is well ventilated, and in the late stages of the disease, where the odor is marked, she should wear at night a skirt of oil cloth or rubber pinned about the waist in order to prevent her being offended by the exhalations rising.

We have already spoken of the method of curetting the uterus and the subsequent application of caustic. This treatment was suggested by Sims but later developed by Van deWarker. It consists in cutting away as much of the diseased tissue as possible, drying the surface and controlling hæmorrhage by packing the vagina with cotton saturated with Monsell's solution. At the end of twenty-four hours this packing is removed, the surface cleansed and then packed with cotton saturated with a solution of chloride of zinc, varying in strength according to the extent of the disease. When there is quite a thick wall, affording opportunity for extensive slough, without destroying immediate structures, a saturated solution may be used. Where the intervening layers are thin, it may be used in the strength of six drachms to the ounce. In using the caustic it is very important to carefully protect the healthy tissues and walls of the vagina by covering it with an ointment consisting of two drachms of bicarbonate of soda with an ounce of cosmoline. The cotton tampons wet with a solution should be carefully squeezed out so as not to have any superfluous fluid to run over the pelvic tissue. A tampon of cotton should be applied below it and then one wet with a saturated solution of bicarbonate of soda. Bicarbonate of soda decomposes chloride of zinc and thus destroys its caustic action. Even with these precautions, however, unless very great care is taken, the superfluous fluid will run over the vagina, giving rise to considerable cauterization of the outlet of the canal. A case occurred in the practice of a gentleman of this city, in which the application of this caustic resulted in a slough of vaginal walls, causing an opening into the bladder and rectum and with an extensive sloughing of the diseased tissue of the uterus. The patient recovered from the operation with a recto-and-vesico-vaginal fistula. The tissues contracted, making the canal so small that it was impossible to dilate it sufficiently to repair and close these fistula. The condition of the patient consequently was a deplorable one; one in

which death would have been preferable.

In the patient we have before us, I do not consider that this plan of treatment would be applicable, for the reason that the intervening wall between the bladder and vagina would be opened, and possibly that also of the rectum. The tampon should be removed at the end of forty-eight hours or earlier, if there are indications of developing sepsis; the patient kept in bed and douches used twice a day subsequently until the slough has completely separated and the surface granulated. Throughout the tenth day it is quite important to have the patient watched carefully for fear that hæmorrhage may result through opening of large vessels from the slough. If there is a tendency to bleeding, the nurse should be directed to use a vinegar douche and this followed, if necessary, by a douche containing the per sulphate of iron. If we are called to see a patient before the disease has extended outside the uterus, or while it is still confined within the organ, whether involving the cervix or the body, the operation, above all others, to be considered is the extirpation of the uterus. To determine the condition, however, and, whether such an operation is suitable, we should not be content with vaginal examination alone, but should always examine by the rectum. By so doing we are enabled to ascertain the extension of the disease to the posterior surface of the broad ligament, the infiltration that would thus result, nodules that may be present and the movability of the uterus.

It is true that operations are done for amputation of the cervix where malignant disease is confined to one or the other lips of the uterus; but when we consider that the disease extends to a greater degree along the mucous membrane, we can readily understand that there may be cells situated above the point at which amputation takes place, which will be the nidus for subsequent development of the disease.

It would seem that the removal of the uterus is just as certainly indicated in cancer of any portion of it, as would be the removal of the entire breast where one lobe of this organ is the seat of malignant disease.

With the importance of rectal examination in such cases, I was very thoroughly impressed some years ago, upon examining a patient whom I had already advised to undergo vaginal hysterectomy. At a second visit she informed me she had considerable irritation of the rectum. I made an examination and found extensive ulceration and infiltration of its wall without any direct indication or connection with disease of the uterus. The presence of this condition in the rectum, precluded, of course, any operation. If I had neglected this, the patient might have been subjected to a hysterectomy, and the rectal trouble overlooked. The extirpation of the uterus by vagina is not necessarily a very dangerous one. In the hands of such men as Martin and Leopold, the mortality has been reduced to but little more than five per cent. The operation is one, in favorable cases, that can be very readily and speedily performed. It consists in making an incision behind the cervix, which is firmly held by a Volsellum, the tissue pushed off in front, and behind, until the peritoneum is reached. The vagina is opened posteriorly and a sponge attached to it to hold up the intestines and prevent the peritoneal cavity from being soiled with blood. The opening is then made through the peritoneum anteriorly, leaving the organ attached by its broad ligaments. Upon the finger, one blade of the modified Greig Smith clamp is passed behind the broad ligament. The other blade is passed in front. These are locked and the external end screwed down, until the broad ligament is thoroughly compressed. This ligament is then cut off close to the clamp, the uterus dragged down, the clamp applied to the opposite side and it cut off as well. The clamps are now held one on either side of the vagina and the sponge withdrawn from the cavity. The vagina may be irrigated, washing out blood, and after drying it, an iodoform gauze tampon is introduced, carrying the gauze carefully upward on either side over the end of the clamp, in this way protecting the intestines from contact with it. The end of both clamps is thus covered, the vagina pretty comfortably packed with gauze and the patient placed in bed. They usually suffer very little inconvenience, and it is but rare that an anodyne is found necessary. The clamps are removed at the end of twenty-four hours; the gauze packing in four or

five days. Some plain gauze or antiseptic cotton is kept over the vulvar outlet to receive the discharges. Usually the discharge is pretty free for the first twenty-four or thirty-six hours. In performing this operation it is very important not to injure the bladder when we cut around the uterus, and particularly important to avoid injury of the ureters, either with the knife or the clamp.

COMMUNICATIONS.

THE TREATMENT OF INCISIONS IN THE ABDOMINAL WALLS, AND VENTRAL HERNIA.

G. D. LADD, M. D., Milwaukee, Wis.*

In closing a wound in the abdominal walls three important points should be considered, viz.: the prevention, if possible, of adhesion of adjacent abdominal viscera to the abdominal parietes; the prevention of ventral hernia; the prevention of stitch abscess and wound infection.

The frequency with which adhesion to the abdominal wound follows laparotomy cannot be accurately determined, but from our knowledge of the behavior of the peritoneum, and from autopsies in cases which have previously recovered from such operation, we can reasonably conclude that it is a very frequent or perhaps usual occurence. That such adhesions are usually productive of no harm or discomfort is attested by the large percentage of cases in which the clinical result shows freedom from all pain or discomfort at this point. It may even be claimed that such adhesions are an advantage in rendering more secure union of the wound. A careful consideration of the condition which obtains where ventral hernia exists shows, however, that such is not the case, for they exert little or no influence in preventing the protrusion and a proper union of the wound is of itself always sufficient toprevent the occurrence.

Adhesion of one or more loops of the small intestine to the abdominal wall is, however, sometimes productive of great discomfort and pain, and, as it is our aim to leave the contents of this cavity in as nearly the normal condition as possible, the prevention of this complication becomes quite an important desideratum.

As any rough handling or injury to the peritoneum near the incision favors adhesion, it is important to avoid this in so far as possible. For this reason the peritoneum should be divided by a careful incision with either the scissors or a sharp knife. In using retractors, or in sponging, care should be taken to avoid all unnecessary rubbing or friction upon this tissue. Morris has demonstrated, in experiments upon animals, that Aristol dusted and rubbed upon any injured portion of the peritoneal surface is innocuous and will prevent adhesion. While its use will not become general in closing these wounds it may be at times of very great service.

Ventral Hernia.—Ventral hernia, although a remote risk, has followed incisions in the abdominal walls and that sometimes in the hands of very skillful surgeons, and its consideration is a matter of importance whenever we close these wounds.

Various modes of applying the sutures have been in vogue at different times and are in favor with different operators. In the early days, and by some at the present time, all of the abdominal wall was included in each suture, and the results were good. Later and by others the sutures were made to include the skin, fascia and peritoneum. More lately the custom has been to include one or more layers in a single set of sutures, the peritoneum, muscles and fascia, and skin being sutured separately.

Whatever plan is followed it is of first importance that the fascia be securely united throughout its entire extent. Failure to properly secure this structure it is that allows a ventral hernia to occur. A good plan to follow is to include the peritoneum, singly, in a continuous suture, next including the muscle and fascia in

*Surgeon to St. Mary's Hospital.

a set of interrupted sutures, and lastly suture the skin separately.

When ventral hernia exists as a result of an incision through the abdominal walls it is because there has been failure to secure complete union of the fascia. The comparatively rare occurrence of this complication is due to the fact that a suture passed through the muscle usually includes the fascia, or it is included in and held by cicatricial tissue. The treatment then, for ventral hernia consists in dissecting out the edges of the fascia, in one or more layers according to its anatomical conformation at the point of incision, and approximating them firmly by frequent interrupted sutures, as many as three to the inch. The edges of the fascia will be found to have retracted and curled up, often being obscured by cicatricial tissue. Frequently a large pocket will have been formed by a gradual separation of two of the layers of muscle, and the surfaces, being constantly subjected to slight friction become infiltrated and smoothed until a fair substitute for a serous surface is established, In proportion as these surfaces have become old and thickened does it become difficult to occlude the cavity. It may be necessary to freshen the surfaces where they will be included in the sutures which close the abdominal wound, thus securing immediate union at this edge. A counter-opening, leading to the surface, at the outer edge of the pocket, will allow of its being packed and subjected to such subsequent treatment as may be necessary.

Prevention of stitch-abscess and wound-infection.—We here touch upon a very broad and interesting subject, but shall not enter into it except to consider a few points lately demonstrated as necessary in order to secure uniformly good results. For the sterilization of instruments and silk a high degree of heat is the one means upon which we can rely. The next factor to be eliminated, taking the steps of an operation in order, is infection from the skin. All are familiar with the methods employed for this purpose and probably, also, with the fact that no matter how carefully and thoroughly they are resorted to there is frequentiy a failure to prevent slight suppuration around the stitch, even when the needle and material used for sutures are aseptic beyond suspicion.

The ordinary cleansing and chemical disinfection, if thoroughly carried out, removes or destroys the many bacteria that are upon the surface of the skin.

Welch, however, describes a coccus often seen by others and identified as the staphylococcus pyogenes albus, but which he individualizes by naming it the staphylococcus epidermis albus, found in the deeper layers of the skin, and which is not reached or destroyed by any known means of cutaneous disinfection save the application of heat.

To obtain cultures of this coccus, silk, proven by previous test to be aseptic, is drawn through skin, which has also been disinfected so that scrapings from its surface give negative results, and placed in a culture medium. That this coccus is productive of only slight and limited suppuration about the stitch is proven by the very limited amount of disturbance which exists where it alone is found. It, however, interferes with the integrity of a wound and may thus allow of more serious disturbance.

In cleansing the hands of the operator and assistants, the prolonged soaking and rubbing of the cuticle in water as hot as can be borne, thus softening and removing the outer layers of epithelium and at the same time applying heat, will greatly aid in rendering the surface germ-free. The method of chemical disinfection which seems to be the most thorough is, after the above cleansing, to soak the hands in a warm saturated solution of permanganate of potash, rubbing them thoroughly; placing them in a warm saturated solution of oxalic acid until completely decolorized; immersing them in a strong solution of corrosive sublimate thereafter.

As living tissues are known to resist the development of bacteria, or to a certain extent dispose of them, it becomes very important that the integrity of the tissues be not interfered with. For this reason, in making an incision the tissues should be nicely divided with a sharp knife, and tearing or stretching avoided. The use of chemical disinfectants within a wound has been found to cause a superficial necrosis which favors, or forms a medium for the multiplication of pyogenic bacteria and should be avoided. In tying sutures care should be taken to avoid constricting the tissues so as to interfere with their nutrition.

In choosing a material for sutures silk seems to answer the requirements better than any other substance. It can be quickly and easily sterilized by heat at the time of operation, undergoing thereby no change in size, strength, or flexibility.

Klemm, by repeated experiments, has demonstrated that catgut can be rendered germ-free and kept so, but that, buried in a wound, this softening non-resistant substance is a favorable medium for the growth of germs. In silk, buried in like manner, few or no germs were found.

The peritoneum then should be closed with a continuous suture of fine silk. The fa-cia and muscle by an interrupted suture of medium sized silk. It has been recommended that the use of skin sutures be abandoned, as excellent coaptation can be obtained by subcutaneous sutures. If skin sutures are used they should be removed early. The usual dry aseptic dressing retained by plasters or a bandage is all that is required.

THE ASEPTIC AND ANTI-SEPTIC CARE OF THE LYING-IN WOMAN AND NEW-BORN CHILD.*

H. G. NORTON, M. D., Trenton, N. J.

Inasmuch as it is our duty as physicians to use every known means to limit maternal and infant mortality during the puerperal period, I shall briefly give my views of the proper conduct of a case of labor and the early care of the child, hoping to bring out valuable discussion on this important subject.

1st. The physician himself should be clean and wear clean clothing. I like to remove the usual coat and put on one of clean white linen. The hands, as a ready means of introducing infection, need special care. It is sufficient, I think, to pare and clean the nails carefully, then wash thoroughly with hot water and soap, using the nail brush vigorously, followed by the free use of a germicide solution and the nail brush.

A very thorough procedure would be after the method of Prof. Keen, viz.: wash the hands with soap and hot water, using the nail brush, then wash in alcohol, then in a permanganate of potash solution, which is to be washed off in an oxalic acid solution. To complete all dip the hands in a bichloride solution.

2nd. Not less important than cleanliness on the part of the physician is a clean nurse. The nurse should wear cotton dresses, not woolen; her hands should be as scrupulously clean as her whole attire. Often, I think, cases of puerperal fever are due to an unclean and untidy nurse rather than to any want of carefulness on the part of the physician.

Many people expect a nurse to aid in the work of the house and of the family, in addition to her care of the mother and child. This we should discourage and explain our reasons therefor to our patients.

As to the woman about to be confined, she should be regarded as a surgical case; be made absolutely clean and prepared several days before the expected confinement by soap and water cleansing of the vulva and a daily immersion bath. Upon the first manifestion of pains give an enema to empty the lower bowel. This removal of feces from the rectum facilitates the birth of the child, makes it pleasanter for the physician, and removes a great source of danger of infection from mother and child; afterward the genitalia must be rendered aseptic by the use of antiseptic solutions.

3d. Give a copious antiseptic vaginal douche and cover the vulva with an antiseptic pad secured in place, then see your patient placed in a clean bed. Here, if it were possible, it would be well to have a cot purposely for confinement, from which the woman could be removed and placed in her bed at the termination of the labor. In any event we must see that the bed is clean and fresh and allow no sheets upon it that have not been laundried since used. Rubber obstetric pads are a great convenience for use during delivery and prevent soiling the bed. Keep the vulva covered with a clean bichloride napkin during labor and after.

When the patient has been properly arranged the physician should make a preliminary vaginal examination after thoroughly disinfecting his hands. As few ex-

*Read before the Mercer Co. Med. Soc., Nov., '92.

aminations as possible should be made. We should endeavor to be guided by external abdominal examinations as far as can be, and even by sight, during the progress of the head, rather than make frequent digital examinations.

After delivery the emptied womb should be regarded as an open wound and treated as such. Examine the perineum at once, and if lacerated repair it; keep the vulva covered with an antiseptic napkin during the continuance of the flow. Don't allow the use of any old pieces of muslin that happen to be at hand for this purpose.

We naturally next turn our attention to the child, and after announcing its sex and assuring the mother that it is not marked, we proceed to take such care of it as will prevent septicæmia from the cord or purulent ophthalmia. Often, I fear, when a child dies within a few days after birth, we complacently give marasmus as the cause, deceiving the parents and still worse ourselves, when it was often, doubtless, due to septicæmia, due to improper care of the cord. Where an infant has fever it is probably septic. Don't tie the cord with any chance piece of string but with a proper ligature which you have with you. We should endeavor to have a dry, rather than a moist gangrene of the cord, to attain which we would not of course allow the nurse to wrap it in a greased rag, but envelop it carefully in an antiseptic dressing of either borated or salycilated cotton, or gauze, and dress it daily; over all should be a soft flannel binder.

We should endeavor to prevent ophthalmia neonatorum by attention to the child as soon as born. Its eyes should be wiped out at once and one drop of a two per cent. solution of nitrate of silver dropped in each eye, after the method of Credè. Where the vagina is carefully syringed before labor infection is less likely to occur.

Not less important is it to know that our forceps and other instruments are antiseptic before using them and there is usually time to make them so. I would boil all instruments likely to be used for five minutes in a clean covered pot, containing a tablespoonful of washing soda to the quart. The use of the soda prevents instruments from rusting, a good thing of itself.

Our obstetric satchel should contain a rubber perineal operating cushion, obstetric forceps, needles and holder, syringe, chloroform, ligatures, antiseptic gauze, catheter, boracic acid, tincture of iodine, and creolin. To properly conduct a case of labor to a successful issue requires the highest skill, tact and knowledge, besides it is very exhausting to the attending physician. In view of these facts we should charge a fee commensurate with good service and make the service worthy of the fee.

SOCIETY REPORTS.

THE MILWAUKEE MEDICAL SOCIETY.

Meeting of November 22nd, 1892.

Dr. G. D. Ladd, Milwaukee, read a paper entitled "The Treatment of Incisions in the Abdominal Walls and Ventral Hernia."(14)

DISCUSSION.

Dr. H. M. Brown: I must take issue with Dr. Ladd as to the cause of ventral hernia following incisions in the abdomen.

He says that ventral hernia as a sequence of operations on the abdominal wall is oftenest due to incomplete coaptation of the edges of the fascia. I would suggest that the experience of a large number of surgeons as collated within the last six months has gone to show that the most frequent cause of ventral hernia, following wounds of the abdominal wall, is the use of the drainage-tube or drainage. The fact that in one hundred and twenty-six consecutive operations in which there was no attempt to bring into coaptation the edges of the fascia, there was no case of ventral hernia, would seem to prove beyond any question the truth of the statement, that ventral hernia is not due to incomplete coaptation of the edges of the fascia. Or, at least, that the question of coaptation of the fascia itself had but a small share in the formation of ventral hernia. There are a great many other causes of

ventral hernia than the lack of coaptation of the edges of the wound; *imprimis*, the question of ptosis of the different viscera. Such cases may arise in old women who have suffered for years from large tumors, multilocular cysts of the ovary, cysts of the broad ligaments, large fibroids, and cases particularly of carcinoma of the viscera of the stomach, or of the ascending colon, where there is a tremendous amount of elongation or prolapse of the viscera by prolongation of the colon, so that the organ is let down against the abdominal wall, and nothing supports the organ except the abdominal wall. So soon as an incision is made through the abdominal wall, that support is taken away and no suturing can be depended upon to give sufficient elastic support to maintain perfect coaptation. Ventral hernia may be caused by a prolapsed kidney, and undoubtedly the ptosis of the abdominal viscera is one of the most frequent causes for the sequent ventral hernia after the operation on the abdominal wall.

The method of suturing wounds by prolonged and continuous sutures through the peritoneum, and ignoring the muscles entirely, and joining or coaptating the skin and suturing it, has not been followed particularly often by ventral hernia. Had the question of the occurrence of ventral hernia, or its non-occurrence, depended upon the coaptation of the fascia, then should ventral hernia have followed every one of these cases.

Ventral hernia is a matter which, as I should think has been pretty well proven by the condition of soldiers during the late war to be largely conditioned upon the physical condition of the individual. In examining the 2264 inmates of the National Soldiers' Home last year, there were found forty-six cases of ventral hernia in men, forty of which were above the umbilicus, and six below. In one case which was regarded as a ventral hernia, there was hernia following an operation on the abdomen for dressing a shell-wound of the abdominal-wall, and, of course, we could get no history in regard to the operation or its method of treatment. This hernia was very large in size.

Another point that Dr. Ladd made in regard to the question of the use of sutures is, I think, worthy of attention. I do not think the number of sutures is of the greatest importance. Dr. Senn, who certainly has had great experience in these matters, and with whose operations I have been familiar, seldom used more than five or six sutures along the abdominal wall, which were passed directly though the whole thickness of the wall from within outward. The abdominal wall was then lifted by means of the sutures, and a sponge used to protect the intestines; this was removed and then the sutures were each separately tied. Then a few superficial stitches closed the wound entirely, and that was the end. I saw many of his cases after the operation and followed them to recovery, and saw no cases of ventral hernia following. My own list of laparotomies is not enormously large, but I have never been obliged to accuse myself of having caused ventral hernia by neglect in regard to the number of stitches, and I seldom use more than four or five in an abdominal wound. If the operation has been done under proper aseptic conditions and has been done properly, there is but little chance that forty-eight hours will go by without there being complete cohesion of the peritoneal surfaces, and but little more is required of the stitches through the abdominal wall than to maintain the surface in coaptation until such effusion of lymph shall have taken place and the wound has been healed from within. Therefore, I think that with each stitch danger increases, and that the fewer we use the better, within reason.

Dr. Solon Marks: I have seen a good many ventral herniæ within the last forty years, and I look upon it that it is hardly necessary to stitch the fascia at all. I think, in the majority of cases, where the sutures are put through the wall entirely and drawn up, that union will take place in a short time. I think there may be cases such as Dr. Ladd has alluded to, where it is absolutely necessary to insert a large number of stitches, but, as a rule, I think the dressing, as described by Dr. Brown, is all that is necessary. I hardly believe that it is necessary to stitch those different fasciæ separately and put in a great number of stitches.

Dr A. J. Puls: I would like to call attention to the following points:

First: The adhesion of the small intestines to the peritoneum, can always be avoided by placing the omentum over the intestines. *Second*: There should be no

antiseptic solution used in the abdominal cavity. Wherever you apply the antiseptic solution within the cavity you are sure to have adhesions of the intestines to the wound surface. *Third*: Abscesses of the abdominal wound I have not met with except in one case, and the fault there arose from my not drawing one stitch (it was the lower stitch) through the abdominal wall. As a rule, I always sew right through the wall from the outside, bringing the needle through on the inner side in the opposite direction, and bring both walls in opposition. I am always careful to get the muscle to come together. I do not care at all about the fascia; I do not see it. *Fourth*: Take in the peritoneum and the muscle and you will always have a good, healthy wound. I have had occasion to open two of my wounds and make a second laparotomy, and I found an exact cicatrix which would not, under any circumstances, allow a ventral hernia. *Fifth*: It is advisable, in order to avoid the possibility of ventral hernia, to secure the wound for at least half a year with straps and bandages.

Dr. Brown: I have had occasion to look up the matter of ventral hernia thoroughly and particularly. I have had four cases within the last year upon which I have operated, and I would like to say a word in regard to fascia. I operated three weeks ago in this hospital (Milwaukee) upon a case where the laparotomy was followed by ventral hernia. The post-mortem examination disclosed a carcinomatous degeneration of the left Fallopian tube. The condition of the hernia in this case is of interest, particularly in relation to what Dr. Ladd has said in regard to the coaptation of the edges of the fascia. This woman had a ventral hernia, which, when she took a deep inspiration or contracted the abdominal wall for the purpose of evacuating the bowels, protruded from the abdomen as large as a four-quart pail, and when she stood erect and threw the bowels back into the abdominal cavity and held them there by a tense condition of the rectal muscles, the hernia was half as large as a child's head. When I attempted to get the history of the case, all I could find out from her was that she had been operated on in Portage two years ago. Five weeks after the operation, the wound not being healed completely, (she had been obliged to go about her household duties,) the whole wound got open except the peritoneal layer. She had been put to bed again, the edges of the wound brought together and junction had taken place, leaving behind this ventral hernia. I endeavored to make the operation by making an incision on the side of the tumor about the circumference of its base, the idea being to split the layer of tissue which covered the bowels, dissect out a piece of the encasement of the tumor, draw the peritoneal margins together and sew the semilunar-shaped flap back in its place, and in that way bring the line of the two incisions at different points in the abdomen, and also to interlace during the process of operation the layers of muscles from the one side of the abdomen with the layers of muscles from the other. But so soon as I made my incision and attempted to split the flap I found it consisted simply of peritoneum, transverse fascia and the skin—there was no muscle there; so I was obliged to make a central incision, dissect off part of the flap and bring the edge of the wound together in the ordinary way. The wound healed perfectly, but the woman died on the eight day of inanition and a post-mortem examination revealed the fact that the intestine had become adherent—long before I had seen the case—to the upper portion of the uterus and its lumens was less than the size of a very small quill at that point. She had taken food which remained in the upper part of the small intestine, none passing through the bowels. She had no temperature and would have made a good recovery except for this contraction of the intestine. It was certainly a case where apparently the transverse fascia had done something towards trying to save the abdominal and had not done it. It was impossible to draw the muscle layers of the two sides of the abdomen together, and there was no elastic tissue whatsoever of the intestine and the abdominal contents, and the hernia was formed. It seems to me that it is far more important that the muscle layers of the abdominal wall should be as nearly as possible placed in their original position for the sake of their elastic characters, than that the inelastic, unyielding, white, fibrous tissue of the transverse fascia should be restored to its place.

Dr. Samuel W. French: In respect to this point of uniting fascia, I would

say that it calls to mind an unfortunate case that I had two years ago, in which I had the stitch abscess the doctor has mentioned, and the whole wound went by the board. The peritoneum, however, had united. The wound had to be filled up from the bottom. I attempted about two months after the operation, to refresh the edges and bring them together by buried sutures, but there evidently was some pus left behind, and the operation was a failure. The patient remained in the hospital some eight months and it was eight months from the time of the operation before the whole wound was healed. I saw the patient a year afterward and there was no ventral hernia. I believe that stitch abscesses come from dirty needles and improperly prepared silk, and no matter how careful we may have been, that there has been something left behind, so much so that in using silk myself I sterilize my silk and my needles upon three successive days if I am going to do a laparotomy. But I do believe that the next time I do laparotomy I shall use the silk worm gut, and I had come to that conclusion some time ago. I have noticed also that another gentleman, a member of this society, who does a great deal of laparotomy work has also come the self-same conclusion, and I understood from him the other day that for some little time back he had used nothing but silk worm gut for the abdominal sutures. I believe this course is sound, because it is perfectly evident that a silk worm gut is a substance that can be more thoroughly sterilized and you are surer about it than you are with silk or braided silk.

Dr. Puls: I favor the use of silk for sutures. I have used silk worm gut for vaginal operations, and I am sorry that I have. I do not like it. It cuts into the tissue, and unless you thread it thoroughly it opens, and if it is too tight it will cut. Silk will never do that.

The point made by Dr. French of sterilizing the needle three times before going through an operation is, in my opinion, altogether erroneous. If he takes his needle and thread and puts them into a sterilizer and leaves them there for ten or fifteen minutes, he will never have stitch abscesses, everything else being in proper condition, and properly done. I have seen gentlemen come with their needles prepared the night before to an operating room, and have heard the method praised, but I think it is unnecessary and wrong.

Dr. A. J. Burgess: A practical point about ventral hernia is that it rarely, if ever, becomes strangulated. Therefore, a surgical operation is not always necessary. The treatment by bandages and trusses is often sufficient and certainly much less dangerous.

Dr. French: If we are ready to believe scientific men on the germs of suppuration, it has been found that there are certain germs of suppuration that fifteen minutes will not kill in the sterilization; and it is therefore necessary, in order to be positively sure that all germs and all spores are killed, to sterilize on three successive days.

Dr. Ladd (closing the discussion): This discussion reminds me of a story which illustrates the point so well that I may be excused for telling it. In a western court a case was brought where a railroad company was defendant. A farmer had carelessly driven across in front of a locomotive of the company and had been struck. The engineer testified that he blew his whistle; the brakeman testified that he heard the whistle blow; but the farmer brought in five men that testified that none of them heard the whistle blow, and the farmer won his case. I have never had a ventral hernia follow an operation. The fact that Dr. Brown cites 126 cases in which it has not occurred proves nothing. It is the case that has ventral hernia that he must investigate to find whether the fascia are finally united. The case of the drainage tube would also be a case where the fascia was not united. He has not brought forward a positive case of ventral hernia to illustrate the point. I do not put three stitches to an inch in a wound after laparotomy. In my paper I refer to operating in case of ventral hernia.

As to suturing the muscle, this undoubtedly is important, and the ordinary way of applying the stitches through the muscle would, almost invariably, include the fascia, which is probably the reason why ventral hernia has not more often followed these operations.

Foreign.—Mr. Murphy—Pwhat is lay greep, Mrs. Flaherty? Mrs. Flaherty—It's me impreshun, Mr. Murphy, that it is wan of thim bloody Oyetelian saysoities.

GYNECOLOGICAL TECHNIQUE AS CARRIED OUT AT THE GYNECEAN HOSPITAL.*

J. M. BALDY, M. D.

It is no uncommon thing to have physicians from all over the country, who are making a temporary stay in Philadelphia, and who are visiting the hospital with the object of seeing operations, question minutely as to the different points in the preparation, and not infrequently express surprise at the simplicity of these. In fact, it has often occurred to me that many of our visitors are more interested in the preparation than in the operation itself. To one who has the success of this class of work at heart, this seems to be a step in the right direction, as it has long since been recognized by the successful operators of the world, that more good results are obtained by mediocre operators, whose preparations have been most careful and systematic, than by their more brilliant colleagues who have been inclined to scoff at minutiæ and to depend upon their mechanical skill.

From time to time articles on this subject have appeared in medical print giving the most elaborate description of the preparation and the apparatus used, most of which are undoubtedly excellent and well-fitted for the operating-room of a hospital, but which are unnecessarily cumbrous when one comes to apply them to private work. For this reason I have been encouraged to enter upon a detailed description of our work at the Gynecean Hospital, the application of which can readily be carried into private practice. The watchwords from the beginning to the end of an operation are *thoroughness* and *simplicity*.

The aim of all successful operators is the same, namely—the prevention of any septic matter entering into the field of operation. Different operators adopt different methods of accomplishing this object, but for success, the object and result must be the same, whatever the method adopted may be.

Antisepsis or *asepsis*, as fancy may dictate, the principle is the same. To be successful one must be surgically clean. For the proper accomplishment of this one must consider and treat: 1. The patient. 2. The operating-room and its paraphernalia, including tables, basins, pitchers, buckets, instruments, ligatures, sponges, dressings. 3. The operator, assistants, and nurses.

1. *The patient.*—The preparation of the patient should begin, when possible, at least twenty-four hours before the operation. The first steps are to regulate the diet and empty the gastro-intestinal tract. Free purgation is begun at once, preferably by the use of some saline. This is usually administered in the dose of a drachm of sulphate of magnesia, dissolved in water, each hour until the bowels begin to move. Usually five or six doses are sufficient to accomplish the object. The purgatives should be so administered that the action of the bowels ceases five or six hours before the time set for the operation. After beginning the administration of the purgative, the diet should be light and concentrated. If the operation is to be performed in the afternoon, the patient's supper on the day before consists of the ordinary house diet. From this time on nothing passes her lips, unless it be a glass of milk or a cup of bouillon at breakfast-time. Even water, except in small quantities, is withheld. These steps in the preparation can be carried out in the case of most patients, but in dealing with an unusually weak woman, considerable judgment must be used in their application. A hot bath is given, both the day before and the morning of the operation. If the patient is unable to be moved to the bathtub, the baths are given in bed. Prior to the final bath an enema of soapsuds and water and a vaginal douche of bichloride of mercury (1 to 3000) are given. Immediately on coming from the bath a fresh night-gown is put upon the patient and she is placed in a bed which has been specially prepared for her reception. After returning to bed the abdomen—the seat of the operation—is especially prepared. A nail-brush, soap and hot water are used freely and vigorously, special attention being paid to the umbilicus and pubic hairs. In but exceptional cases is the pubes shaved. The abdomen is then bathed with alcohol and turpentine

*[Read before the Philadelphia County Medical Society, December 28, 1892.]

and is finally protected until the time of the operation with a towel wrung out of bichloride solution.

When the patient is placed on the operating table the abdomen is well rubbed with ether and bathed with alcohol by the operator as the final preparation, especial attention being paid to the pubic hairs and the umbilicus. The legs are wrapped in a blanket, which extends from the feet to the pubes; a second blanket is placed over the chest. All blankets, clothing, table, etc., about the patient from her chest to her feet are now covered with towels prepared for the purpose, the abdomen being left bare from the epigastrium to the pubes. Over all this is placed a piece of bichloride gauze, with a slit in it at the point of the incision.

In the preparation, the room is first stripped of all its furniture. The walls, ceiling, and floor are washed down with a hose, and then mopped off with a cloth dipped in bichloride solution. As each article is brought into the room it is scrubbed with soap and water, rinsed off, mopped with bichloride solution, and placed in its proper position; the tables and benches are covered with sheets or towels especially prepared for this purpose. A glance at the accompanying cut will more clearly demonstrate this. All linen used in the operating-room has been laundried by itself. Distilled water is used throughout the operation.

Instruments.—After an operation the instruments are thoroughly scrubbed with soap and water, and are then passed through

2. *The Operating-room and its Paraphernalia.*—All tables used in the operating-room with the exception of the Krug frame for Trendelenburg's position, which is of galvanized iron, are made of wood, perfectly plain and shellacked. The reason for this is two-fold—first, because it is desirable in the preparation of the room that it should be emptied; this is rendered possible in the case of everything except the gas fixture and the sink. Secondly, as there is an operating-room on each floor, it becomes necessary to frequently move the tables from one room to the other. When not in use, the windows in these rooms are always open. The walls of the room from floor to ceiling are of white tile, the window trimmings are of white marble, the floors are asphalt, the ceilings are plastered and heavily painted.

scalding water before being returned to the case. Prior to the operation they are boiled for twenty minutes in a weak soda solution. As few instruments as possible are used. In an ordinary operation two needles, two ligature staffs, four hemostatic forceps, a knife, a needle-holder, and a pair of scissors are amply sufficient. These, are taken, together with the tray on which they are placed for boiling, directly from the sterilizer, and put upon the table as the patient is brought into the room. In this way they are not handled from the time they are taken out of the sterilizer until they are to be used.

Ligatures.—Three varieties of ligatures are employed—silk, silkworm-gut, and catgut. A half-hour before the operation the silk is immersed in a bichloride solution (1 to 100); prior to being used it is

washed in boiling water. The silkworm-gut is boiled with the instruments. The catgut is prepared by being immersed in ether for forty-eight hours, soaked for the same length of time in a 1 to 100 alcoholic solution of bichloride of mercury, after which it is put in a solution of two parts oil of juniper and one part alcohol. It is taken directly from the latter solution for use at the operation.

All sutures and ligatures used within the abdominal cavity are of silk (Chinese twist.) Silkworm-gut is invariably used for closing the abdominal wound. Catgut is used principally in vaginal hysterectomy and plastic work.

Sponges.— New sponges are prepared by being thoroughly beaten, soaked for twenty-four hours in a weak solution (3 per cent.) of hydrochloric acid, after which they are soaked for twenty-four hours in a strong soda solution, and are finally placed in alcohol. Immediately after being used in an operation they are thoroughly washed in cold water, placed in a strong soda solution (practically a saturated solution) for twenty-four hours, at the end of which time they are removed, washed under the cold-water spigot until all the soda is washed away, and are then immersed in a solution of sulphurous acid for twenty-four hours. They are taken directly from the acid solution, washed, and placed in commercial alcohol until used. Four sponges only are used at each operation.

Dressings.—The dressing of the abdominal wound consists in placing several strips of dry bichloride gauze directly over the incision, a cotton pad covered over with gauze placed over this, and the whole held in place by a six-tailed bandage. Dressing are not disturbed for eight days. No iodoform or other powder is used. Stitch-hole abscesses are the rare exception.

Draining-tubes.—After being used, the glass drainage-tubes are soaked in strong soda solution for twenty-four hours, rinsed under the spigot, washed with turpentine and ether, and then boiled for twenty minutes, after which they are kept in commercial alcohol.

Rubber drainage-tube, whenever used, is soaked in bichloride solution, and washed in boiling water.

After an operation the drainage-tube is cleaned by the nurse every fifteen minutes or half-hour, as occasion requires. As the fluid discharged from the tube lessens in quantity, the intervals of cleaning are lengthened. Each time the tube is cleaned the nurse's hands are carefully prepared with soap and water and bichloride solution.

At and after each cleaning the syringe used to withdraw the tube-contents is cleaned inside and out with hot water and bichloride solution, as are also the mouth of the tube and the rubber protecting it. Fresh bichloride cotton is placed over the entrance of the tube at each cleaning. The tube is removed as soon as the contents become clear and small in quantity. The edges of the opening left by the tube are drawn together by a strip of adhesive plaster, and the dressings replaced by fresh ones.

3. The Operator, Assistant and Nurses.—Everbody who takes part in an operation, and is liable during its performance to handle any of the instruments or materials, is required to go through the same preparation. All assistance is rendered by three nurses; the chief nurse assisting the operator directly, a second nurse attending to the sponges, and a third nurse changing the waters. The preparation of operator and nurses is as follows: a hot soap bath, and clean linen clothing direct from the wash. The hands and arms are prepared by first carefully cleansing the nails with a penknife, a free use of hot water, soap, and nail-brush for twenty minutes, and rinsing in fresh water. They are then bathed in commercial alcohol, and are finally soaked in a bichloride solution (1 to 2000) for five minutes. The greatest danger-point of infection is, of course, under the nails, and time used in a most careful hand toilet is never misspent—is, in fact, absolutely essential to success.

A careful study of the cut, which represents one of the operating-rooms as it appears prior to the introduction of the patient, will demonstrate the simplicity and thoroughness of all the preparations. There is not an article in the room which cannot be duplicated or easily substituted in any well-ordered household. Soap, water, nail-brush, and bichloride of mercury tablets are easily obtained, and as for the remainder it rests entirely with the surgeon and his nurse. With a little more time and trouble the poorest hovel

can be turned into a good and safe operating-room, by adopting these rules, as I have been able to demonstrate time after time in my work in the slums of this great city. Of course, it means plenty of hard labor for both nurse and surgeon, but what nurse or surgeon who has once passed through the horrors of attendance at a death from septic peritonitis would not feel that the work before the operation was as nothing in comparison to that afterward.

The number of instruments, sponges, etc., may seem to many to be entirely inadequate for the purpose, but in many hundreds of operations we have found them amply sufficient; it is the rare exception that recourse to the instrument-case is necessary. The fewer articles used the fewer sources of possible infection and accident. A large number of instruments lying about are, in addition, a source of endless confusion and annoyance, and they require an extra assistant.

Hæmorrhoids.

In an article concerning "Reconstruction of the Pelvic Structures in Women," Dr. H. Marcy, of Boston (*American Journal Obstetrics*, for November), writes:

The pathological conditions which pertain to the rectal tissues result in very large degree from changes in the vascularization, dependent upon the dilation of the hæmorrhoidal veins. These are often deformed to an extent rarely appreciated by the ordinary practitioner, and only to be truly understood by the surgeon who makes the vivisection for the purpose of cure.

I am constrained to believe, as I think for abundant reason, that the ligature and cautery, destruction of the tissues by acids, etc., are not alone unsurgical and barbarous, but they also often fail in the end of securing the desired result, since a portion of the deformed structures not seldom remain unchanged, and tissues of importance to preserve are thereby frequently destroyed.

A complete dissection of the deformed hæmorrhoidal plexus, as advocated by Mr. Whitehead, offers in my judgment abundant reason for adoption, and the only criticism which I have to make upon his method is the closure of the wound with interrupted sutures. This method has been severely criticised, and has failed in great measure of general adoption because of the fear of hemorrhage which during the indefinite pass has been emphasized as liable to pertain to any of the methods applicable to the cure of hæmorrhoids. This is doubtless greatly overestimated by the profession at large.

The dilatation of the hæmorrhoidal plexus is, indeed, sometimes truly enormous, but it will be found upon dissection that the vessels quite within the grasp of the sphincter are usually very little changed, and that here their constriction is simple and easy. I have for some years operated in a way to be commended as in large measures bloodless and assuredly without danger of subsequent hæmorrhage.

The procedure is briefly as follows: The sphincter muscle is dilated and the parts put on tension by two fingers in the rectum. Either with a sharp knife or scissors division is made upon the line of the juncture of the skin and mucous membrane. With a little care the veins are separated from the loose folds of connective tissue without injury, down to the line of the sphincter muscle. They will be found closely connected with the everted thickened mucous membrane, a portion of which it is well to remove. Division should be made through it upon the line selected for incision, and a row of continuous double tendon sutures is rapidly made to encircle the base of the hæmorrhoidal plexus. It is then resected with scissors, and a light line of continuous running sutures encloses the deeper layer, and when drawn upon gently, taken, as advised, from within outward, are themselves buried, thus leaving no stitches in sight. Carefully dried and dusted with iodoform, the operation is completed by painting the line of closure with a layer of iodoform-collodion. It is usually better that three or four days elapse before defecation ensues, after which there is little suffering. With the paralyzed muscle at rest, the condition of the parts remaining aseptic, pain and edema are almost wanting.—*Md. Med. Journal.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316-18-20 North Broad Street
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JANUARY 7TH, 1893.

EDITORIAL.

With this issue THE MEDICAL AND SURGICAL REPORTER enters upon its forty-first year of continuous publication. Every effort will be made to meet the growing demands of modern medical journalism and at the same time retain the highly practical character that has always distinguished this magazine. There are in the field to-day medical journals and medical journals, but few in which the effort is made to supply the profession with accurate, reliable information of the progress of the science and art of medicine and surgery.

The many intersperse clippings from the few between columns of a gorgeous variety of advertisements. Advertising incidental to medicine is a factor in progress. Medicine incidental to advertising is clap-trap. THE MEDICAL AND SURGICAL REPORTER has always been one of the few and has acquired to a rare degree the confidence of the profession. It will never knowingly sacrifice nor impair this trust.

As its name signifies its mission is to report as far as possible the latest and best achievements in the whole field of medicine and surgery. The evolution of medical science has so developed along special lines that it is manifestly impossible for any one journal to cover in detail all branches of medicine and surgery and remain within reasonable limits.

The busy practitioner demands information that he can immediately turn to practical use. Where his opportunities of frequent association with large bodies of his fellow practitioners are limited he must depend on his journals for information that will enable him to keep abreast of the times.

The general practitioner, who to a certain extent is a specialist in all lines, has not the time to read, if he has the means to procure, special journals for each branch. Recognizing this condition THE MEDICAL AND SURGICAL REPORTER will in the coming year supply periodically a series of monographs. These will be in the form of supplements to the regular editions of the magazine. Each monograph, written by a specialist eminent in his line, will be devoted to one subject treated in greater detail than is practicable in the regular columns. Another feature will be a care-

ful review of the contents of the best special periodicals under a department of Current Literature Reviewed. In the matter of Book Reviews an impartial critical statement will be made. This department will be conducted for the information and advice of the readers of the REPORTER wholly independent of other considerations. The Editorial Department will maintain an independent position, free to discuss or comment on such matters as may be of interest to our patrons.

THE REPORTER will not be subservient to any individuals, cliques, or institutions whatever, but will be solely of the profession, for the profession, by the profession.

A word to our advertisers—no advertisements are admitted to our columns except such as after keen scrutiny we feel satisfied are perfectly reliable. That an advertisement does not appear in THE REPORTER is no measure of its value, but one that does appear in its pages may be regarded as perfectly reliable.

The policy of THE REPORTER which bars promiscuous advertisers is not such short sighted business as might appear. Our advertisers have learned the value of a medium that possesses the confidence of its readers, and THE REPORTER sees no reason to doubt the wisdom nor to change the course heretofore pursued. THE REPORTER commends to the kind consideration of the profession every interest represented in the advertising spaces.

Periodical Intermenstrual Pains.

Dr. C. D. Palmer (*New York Medical Journal*) says:

The symptoms of such a condition are principally attacks of pain, coming on generally about the middle of the intermenstrual period, and most severe in the region of the ovaries. Sometimes the pain is confined to one ovary, or both may be involved in the paroxysm. The attacks are irregular in severity and duration, usually intermittent, occurring at night or through the day. Their duration may be from two to nine days. They are not influenced by bodily exertion nor attended by febrile phenomena. As to the cause of such ovarian pain, neuralgia has been suggested as a probable factor, but, if this be the case, why is it that pain does not occur during the regular menstrual period, as at that time women are especially susceptible to pelvic pains? The periodicity of the pain first led to a suspicion of malarial poisoning in these cases, but this theory was soon abandoned when it was found that the attacks were not at all influenced by the most potent antiperiodics. I am not inclined to think there is a structural change in the ovary to account for the pain, although the form, size, or even density of the organ may not be so altered as to make the change discoverable before removal. The condition may be an oöphoritis, a peri-oöphoritis, and interstitial oöphoritis, or a follicular oöphoritis, or several of the tissues may be involved in the degenerative process. There is likely to be hardening of the organ, which interferes with the rupture of the follicle; this may be one cause of pain. There is no reason why the pain may not occur before the menstrual flow, on account of the increased vascularity of the ovary at such a time. The severity of the pain may be out of proportion to the pathological change and nerve pressure. When the congestion subsides, the pain is usually relieved. Various measures have been resorted to for giving relief, some of which have been more or less effective temporarily. In some cases, however, the suffering will be of such character, and the life of the woman be made so miserable, that the question is forced on the gynecologist whether it would not be the proper thing to remove the ovaries in such a case, even though to the touch they seem normal.

Syphilis, after a number of years in the system, becomes detritus—not the disease *per se*—and needs a solvent plan of treatment, not a germicidal.

TRANSLATIONS.

POST-OPERATIVE INTESTINAL OBSTRUCTION.

MARIE B. WERNER, M. D.

Championnière reports six cases treated successfully by operation. (*Bull. et mèm. de la soc. de chirur. de Paris T.* xviii page 102).

1st Case. Ovariotomy; patient æt 35. Four days after the operation symptoms of obstruction set in, gradually increasing in severity. Reopening the abdominal wound on the tenth day various coils of intestines are found to be adherent to one another, one being twisted twice, forming a circular constriction around another. Carefully releasing the adhesions, the abdomen was closed, followed two hours later by a copious bowel movement. Recovery.

2nd Case. Radical operation for incarcerated gangrenous omental hernia. The patient did well up to the 14th day, after that violent abdominal pain set in, vomiting and increased temperature. Vomiting increased until it became fæcal in character. Abdomen distended above the umbilicus where a circumscribed hard mass could be felt. Second operation done on the 21st day. A large abscess was found surrounded by intestines and covered by the omentum; drainage and recovery.

3rd and 4th Case. Radical operation for left inguinal hernia; recovery takes place; pains, however, appear in the right inguinal region, accompanied with moderate swelling, vomiting and constipation. Four weeks after the operation it became necessary to make an incision over the right inguinal canal. A small amount of fluid is evacuated, but the intestines are seen to be adherent to the swelling, which made it advisable to open in the median line and approach the swelling from the inside. This proved to be an incarcerated loop at the internal inguinal ring which had become almost gangrenous. Close to this there was also an abscess. The median incision was closed; the one on the right was tamponed. Recovery.

Two and a-half months later symptoms of ileus again set in. Laparotomy; incision over the right inguinal canal and release of many dense adhesions. The day following, a copious movement. The abdomen, however, increased in distension, making it necessary to perform inguinal colotomy. Recovery; discharged with fistula.

5th Case. Radical operation for a congenital left inguinal hernia with resection of a large portion of the omentum. Case progressed favorably until the ninth day when symptoms of ileus set in; constipation, vomiting and fever, 38.8° C. A painful swelling can be felt in the right iliac fossa. On the nineteenth day an incision is made into the swelling, a large amount of extravasated blood is evacuated, the sac cleansed and drained; rapid recovery.

6th Case. Herniotomy for incarcerated intestines. A small perforation was discovered and closed; healing. After a time colicky pains; constipation and tympanitic distension of the abdomen appeared. These symptoms increased until there was no doubt of its being caused by ileus. Laparotomy; that portion of the gut which had been sutured was found tightly adherent to the abdominal wall, its calibre markedly lessened by its angular position. In order to avoid enterorhaphie Championniére dissected the intestine from the abdominal wall leaving both peritoneal coats intact at the points of adhesion; recovery complete.

Championniére is decidedly opposed to the administration of opiates in any form after any abdominal operation. He is particularly anxious to have an early action of the bowels and in certain cases has been known to give laxatives on the evening of the day of operation, and feels certain it will rather lessen than favor the danger of peritonitis, in that early peristalsis often prevents incarcerations, adhesions or paralysis of the intestine. He also condemns the use of opiates in cases of strangulation of the bowel, feeling certain that the early exhibition of laxatives has often led to an early diagnosis.

*Translated for Medical and Surgical Reporter.

A Case of Living Xiphopagus.

Hr. Marcel Bandowin reported in the *Paris Academie of Sciences* the case of two girls of three years and two months, being united from the xyphoid process to the umbilicus in the regio sub-umbilica. They were born in the East Indies, and make the eighth case of xiphopagus reported. A careful examination proved that neither presented inversis viscerum; which proves that the lower division of the true xiphopagi and thorakopagi have been properly described by Dareste who presented their origin in the following manner. If in one ôvum two fertilized nuclei develop in a parallel line at the same time, a double monstrosity results, the xiphopagus; both primitive lines must at first be distinctly separate, one at each pole of the ovum; when the embryos, well developed, become larger, they face each other and the upper regions of the body come in contact. Surgical treatment in these cases is advisable. In fact, indicated, for should one of the sisters become fatally ill the chances of saving the other would be greatly lessened. Even should there be union of the liver, adhesions or even anastomosis of the intestines (which is not improbable), the operation might produce a doubly good result.

It has been performed several times (?) by Kœnig with a good result and ce by Bœhm-Gunzenhausen, on his own daughter, with partial good results; the one living five years after the operation.

Resection of the Left Lobe of the Liver for Cancer.

Prof. von Licke (*Central-blatt. f. Chirurg.* 41, 1892) reported in the *Centrabl. f. Chirur.*'91, No. 6, p.115, this case in detail and wishes to report the present condition of the patient. Two years have elapsed since the operation, the patient has been constantly under observation, and frequently examined. During the past summer she became much emaciated, and suffered from loss of appetite and frequent vomiting and distension in the gastric region; a return was suspected; the cicatrix, however, was healthy and the most careful examination disclosed no tumor of either liver or stomach. By exclusion it was concluded that her emaciation and its concomitant symptoms was due to her impoverished circumstances, the good diet and care she received with her visible improvement in strength and weight seemed to substantiate our conclusions.

At the present time a careful examination proves the *total absence of any return in the organ operated upon for more than two years.*

ABSTRACTS.

CHOLERA EPIDEMIC OF 1892.

In an editorial retrospect of the past year the *Boston Medical and Surgical Journal* says:

"In recent years, when cholera has reached Europe, it has generally come by the way of the Suez Canal. This was the case in the outbreak in 1890, in Spain. In 1891 no cases was reported in Europe. It had, however, come through the Red Sea ports into the Hedjaz, during religious ceremonies in Mecca, and had spread through Asia Minor. In the first of the year cases still occurred in different parts of Asia Minor, but by the middle of February it has disappeared from the neighborhood of Damascus and Beyrout, and existed only in one or two interior valleys. This year the religious pilgrimage to Mecca was not attended by cholera.

The epidemic of this year appeared in March, in the northwestern provinces of India. It is obligatory on every Hindoo to bathe in the Ganges where it issues from the mountains. The dying Hindoo, also, is immersed in this stream, if it is possible to get him there, and this point is always considered a cholera focus. The water this year was very low, and the bathing-place was reduced to a pool. On March 22d the first case occurred at Hurdwar, and on the 25th the fair was closed by the police authorities. The dis-

ease was spread by returning pilgrims through the Punjaub, and reached Delhi on March 30th. From here it spread through the Cashmere Valley, and reached Afghanistan on April 15th, and it reached Persia in May. In June it crossed the Caspian Sea, and in July spread among the population of Asiatic Russia. By the middle of the month it reached the Caucasus and crossed into European Russia. It was at this time especially virulent at Teheran and Astrakhan and in the Caucasus. It advanced steadily through Russia, reaching Moscow and St. Petersburg by the middle of July. Until this time no cases had been reported west of Russia except in Paris and these cases in Paris were not a part of the invading epidemic. From April 5th up to July 25th about 160 deaths from a rapidly fatal diarrhœal affection had been reported in the neighborhood of Paris, and the character of the disease, although attributed to the use of Seine water, and manifesting itself in those quarters where that water is supplied for consumption, bore such a striking resemblance to Asiatic cholera, that its identity was during the whole summer a subject of dispute. This disease, which was popularly called cholerine, had existed as an endemic outbreak to a less extent in previous summers. In the autumn, after cases of undoubted Asiatic cholera had occurred in northern France, the attempt to distinguish between the two diseases was abandoned,.

In regard to the origin of the cholera in Hamburg, Havre and Antwerp, nothing positive is known. The infection of Hamburg may have come by rail through Germany, with Russian immigrants on their way to America, or it may have come by sea from Russia or from India. All of these suppositions were discussed. The authorities of Hamburg discovered the true character of the disease on the 22d of August, and announced it on the 24th. It was found to exist in Havre and Antwerp within a few days of the same time. During the next week isolated cases made their appearance in many cities, the cases being almost all easily traced as imported from Hamburg. Several cases occurred in Berlin, some in other North German cities, some in different English seaport towns, all of the latter being in persons directly from Hamburg. Such isolated cases continued to occur during the first half of September, diminishing in frequency. In Hamburg the epidemic increased very rapidly and with a great mortality. Although the highest point in mortality was reached in the week ending September 3d, when 4,168 deaths, of which 3,710 were from cholera, were reported, making a death-rate of 340.8, nevertheless, for some time the decline was slow, but after the last week in September fell rapidly. In Havre the epidemic was not nearly so great, the number of cases a day about the first of September being from 25 to 100.

The extension of the epidemic crossed the Austrian frontier some weeks later, a few hundred cases being reported, especially in Austrian Poland. It appeared in Buda-Pesth early in November, and continued into December. In the whole Austrian Empire 1,000 cases and 500 deaths may be estimated as the number during the autumn. On November 1st, Hamburg was declared free from cholera, but in November four deaths occurred and in the last half of December a fresh outbreak occurred, about forty cases being reported up to the present time. The official statistics in October gave the number of cases as about 18,000 with 7,600 deaths. In Havre, the number of cases from July 15th to October 15th was given as 1,298, and that of the deaths 523. This includes a few cases which were later classed as cholera although occurring before the outbreak was recognized. During November a few cases were reported from different parts of France, 104 in Holland, 33 in Belgium, whereas in Germany there were none except the four in Hamburg. In Russia the epidemic was much more serious and persistent, many districts were revisited after the epidemic had apparently declined. After the 1st of November the disease as a whole was much less serious in the Empire, but the total number of cases reported remains considerable even up to the present time. The estimate of 300,000 deaths is commonly considered as less than the actual fact. The efforts of the sanitary authorities were very much hampered by popular uprisings and in some cities serious riots occurred in consequence of the attempt to enforce sanitary regulations.

Cholera was imported into the New York quarantine directly from Hamburg. The first infected steamer to arrive, the

Normannia, left Hamburg just before the official announcement of the existence of an epidemic. Within a week two more steamers, the *Moravia* and *Rugia*, and latter the *Scandia*, reached New York thoroughly infected. The number of deaths at sea had been 63 and a still larger number were either suffering from the disease on arrival or came down with it shortly afterwards in quarantine. The number of passengers detained from this cause was very large, far beyond the capacity of the New York quarantine station. After keeping the cabin passengers, who with a few exceptions had been free from cholera, for several days upon the infected ships, a steamer was hired by private liberality to accommodate them, and Fire Island bought as a place of detention. The inadequacy of the quarantine station and the bungling of the whole matter may be understood by following the subject as it appeared from week to week in the JOURNAL. A few cases, a dozen or more, with five deaths occurred in the city; their source is doubtful but is more probably due to contagion introduced by passengers from an earlier steamer which sailed from Hamburg on Aug. 14th, than that it escaped from the quarantine.

INTESTINAL OBSTRUCTION: SOME CURIOUS CASES.

George Buchanan, Professor of Clinical Surgery in the University of Glasgow, in *The British Medical Journal* says:

"Diseases of the rectum are, of all surgical affections, among those which are most frequently neglected in their early stages, and so are allowed to assume a condition of considerable gravity before treatment is resorted to. This arises from various causes. Many persons, especially females, have great disinclination to have that part of the body made the subject of observation and examination, till compelled by their suffering to resort to a medical opinion; at least, that has often happened in my experience. Again, many imagine that all disorders of the intestinal tract arise from indigestion, biliousness, or habitual constipation, which they imagine can be removed by the use of familiar laxative medicines, and these they use with all diligence till they prove ineffectual; and if by pain and other discomfort they feel that there is something wrong at the lower end of the bowel, they assume that it is a "touch of the piles," which can be cured by some of the pills and ointments so frequently advertised. One can scarcely take up a newspaper, especially provincial, colonial, or American, without observing the numerous advertisements of remedies vaunted as cures for such ailments; and I believe that the extensive use of these remedies arises from the disinclination, to which I have referred, to submit these complaints in the first instance to the regular practitioner.

But while this is so, not infrequently neglect of radical treatment can be traced to errors in diagnosis, sometimes, though not always, the fault of the medical attendant, who is apt to be thrown off his guard by erroneous descriptions of the symptoms given by the patient. One or two examples of this will follow.

The term "intestinal obstruction" in the present day is used rather vaguely. Under it are included cases presenting symptoms, or groups of symptoms, which are present when there is real occlusion of the intestinal tube, but which are sometimes present when there is no actual obstruction at all, but which depend on some functional deficiency, such as loss of the peristalic action of the bowel, either with or without flatus; of that I have seen several instances. In a discussion which took place in the Medico-Chirurgical Society of Glasgow last winter on intestinal obstruction, numerous examples of spontaneous recovery were cited, and some of these in circumstances which precluded the idea of there having been even temporary local occlusion of the tube. I mention these to point out that such instances were not recoveries from actual intestinal obstruction, but from symptoms identical with those of that condition.

Taking the term in its strict etymological sense, the most constant and obvious symptom is inability to pass fæces; but in the great majority of cases, symptoms of far graver import come on, long before that is of any importance. It is just in cases in which these serious symptoms,

such as obstinate vomiting and failure of the vital powers, are early prominent, that spontaneous recoveries have been most frequent. It is also this fact that renders the question of operative interference so difficult to decide.

The foregoing observations, which are applicable to intestinal obstruction generally, are more or less illustrated in the following examples:

Case 1. *Symptoms of Obstruction: Peritonitis with Effusion: Abdominal Section: Recovery.*—Some years ago I was called to see a domestic, aged about 30, suffering acute symptoms of intestinal obstruction, which had come on rather suddenly after a heavy meal some twenty-four hours before. Pain in the abdomen; obstinate vomiting, stercoraceous; cold skin, flagging pulse; no flatus. I could not form any accurate diagnosis, but felt satisfied that there was no course open to me but abdominal section. No obstruction could be found, but the peritoneal cavity was full of acrid greenish effusion, and the bowels partially glued together with recent lymph. I washed out the cavity with a stream of tepid water. The patient made a rapid recovery and is now the mother of a family.

Case II. *Symptoms of Obstruction: Abdominal Section: No Discoverable Cause: Death.*—Lady, aged about 20, with symptoms somewhat as above, but not so rapid or acute. There was no flatus, but the vomiting was continuous and non-stercoraceous. I performed abdominal section. There was no obstruction; the intestines were quite flaccid, and contained very little fluid; and the peritoneum was quite healthy. She died next day.

Case III. *Symptoms of Obstruction: Apparent Failure of Enemata followed shortly by Relief, and Recovery.*—An old gentleman with symptoms of intestinal obstruction. Constipation had existed for some days, and now there was pain in the abdomen, flatus, and obstinate vomiting. I examined the rectum and washed it out with tepid water, using a long tube and a forcing pump. There was no evidence of any fæcal impaction, the water returning as it was introduced. I could not find any abnormal condition of the intestinal tube, but, the symptoms becoming more grave, I proposed abdominal section as a last resort. The patient agreed, but asked me to bring in consultation a physician with whom he was acquainted. I did so and we agreed that, if he should have the same opinion the operation should be done at his visit. I returned with my friend three or four hours after, when to my surprise I found my patient greatly relieved. He had had a copious evacuation in the interval, and the vomiting had ceased. He made a rapid and good recovery.

Case IV. *Obstruction: Suspected Epithelioma: Removal of Impacted Fæces: Rapid Recovery.*—A lady, 30 years of age, troubled with constipation for some time, accompanied with much pain in the rectum. Latterly, the pain in attempting defæcation was so great that, practically, she had passed nothing for some time but discolored mucous and sometimes blood. For some days she had been troubled with vomiting whenever she took any nourishment. Her medical attendant, discovering that the symptoms arose from some obstruction in the rectum, endeavored to make an examination, but the pain was so great, that the patient would only allow a very partial exploration to be made, either *per rectum* or *per vaginam*. Enough was felt to lead to the opinion that the rectum was occluded by an epithelial growth, which extended far up the gut and bulged the recto-vaginal septum into the vagina. Some surgical operation was urgently demanded—either excision of the rectal tumor, or the making of an artificial anus. As the patient could not suffer a preliminary examination, it was arranged that I should put her under chloroform, make a thorough examination, and proceed as I might find matters required.

The patient was placed on a table, and put under chloroform. On introducing my finger into the retum I found it occluded by a large mass of firm unyielding material, either adhering to or firmly grasped by the walls of the bowel. But it had not the feel of an epithelioma. It was smooth and globular. I could not tear it with my finger, and there was no channel through it for fæces to pass through, and it did not bleed. I had no doubt it was a mass of hardened fæces, and the smell from my finger nail made it certain. I now with my thumbs dilated the sphincter ani as far as it would stretch, and, getting a horn spoon, tried to lever it out. It was too large and firmly fixed for that. The medical practitioner,

who lived in the adjoining house, went for his obstetric bag, and I chose a long, narrow-bladed fenestrated forceps, which is used in craniotomy. I passed a blade on each side, and, by putting on firm traction, removed a large gobular mass of firm, tough material as large as a full sized orange. Another mass as large as a turkey's egg was impacted above that, and was removed in the same way. A third the size of a hen's egg was impacted still higher up, and that was also removed, and the passage was cleared. I now injected a basinful of soapy tepid water, which came away with a few bits of scybala. The patient was practically well, and she has remained so ever since.

Case V. *Obstruction due to Impacted Fæces.*—A man who had had symptoms of obstruction for some time, but only on the day I saw him had vomiting come on. The medical attendant believed that the rectum was obstructed by an epithelial growth, and called me to perform some operation for its relief. On examination I found that the rectum was blocked by an enormous mass of hardened fæces. As the house was not suitable for operations and the symptoms were not dangerous, I gave a subcutaneous injection of morphine, and ordered the patient to be sent to the Western Infirmary, and next morning, broke up and removed the mass, which was about the size of two closed fists.

Case VI. *Obstruction due to Impacted Masses of Calcined Magnesia.*—A case which occured some years ago, I mention from the unusual nature of the obstructing mass. It was composed of hard masses, the size of walnuts, with facets caused by long mutual pressure. They were concretions of calcined magnesia, which the patient had long been in the habit of using as a laxative.

We caution against allowing patients to use calcined magnesia habitually.

It is not often that an opposite error of diagnosis occurs, but the following case is a good illustration:

Case VII. *Diagnosis of Epithelioma: Revised Diagnosis of Intestinal Atony: Recovery.*—A middle-aged gentleman, of sedentary habits, had for many months suffered from some anomalous symptoms —indigestion, flatulence, occasional vomiting, and obstinate constipation alternating with looseness, the stools being often simply discolored mucous. His medical man had ordered some tonic remedies for dyspepsia; but, as he did not improve, he consulted a surgeon with whom he was personally acquainted. The surgeon examined him *per rectum*, and told him that he had an epithelial growth far up; that it was out of reach of any operation for its removal; that there was no hope of his recovery; that his progress downward would be gradual; but that at no distant date he must decide whether he would submit to undergo an operation for the formation of an artificial anus or await his end, which could not be very far off. His medical attendant was unable to acquiesce in this opinion, and, before accepting it, brought him to me. I made a most careful exploration of the rectum, but I could find no growth, stricture, or any kind of obstruction; indeed, the mucous membrane seemed to me more flaccid and folded than usual, and in one of the folds I felt a small piece of hardened fæces, which seemed adherent or retained in the fold. I came to the conclusion that the symptoms arose from atony of the intestinal tube from end to end, with possibly some softening, in parts, of the mucous lining, and specially of the lower end of the colon and rectum. I recommended that he should give up business for two or three months and go to Spa in Belgium, and gave him a letter to my friend Dr. Thomson, indicating my opinion and the treatment I thought would benefit him. The result proved more fortunate than I could have anticipated from the use of the chalybeate waters and the change of climate and diet. My patient came home practically well, and has continued so ever since: that is, for more than two years.

A large percentage of the candidates for admission to the military schools of America are rejected on "tobacco hearts."

In chronic suppurative otitis, so long as the offensive odor continues, the treatment is not succeeding.

French medical observers are of the opinion that the offspring of inveterate tobacco users often greatly lack the normal power of resisting disease, chiefly through the transmission of defective nervous systems, and that they are largely deficient in physicial development.

THE EQUITABLE RESPONSIBILITY OF INEBRITY.

In the Journal of Nervous and Mental Diseases, December, Dr. T. L. Wright in a carefully prepared paper on this subject states that he selects the term *inebriate* responsibility because there is no settled responsibility for the acts of mere drunkenness.

Drunkenness is a form of insanity and is practically so recognized by the law. There is no definition of insanity, nor can there be. The *sane* cannot conceive the *insane*; and hence it cannot define the insane. It can only describe phenomena; but it is unable to point out the logical connections between the phenomena of insanity and their moving cause. The rule of responsibility for inebriates differs in civil from that in criminal cases. We will consider the responsibility of inebriates for criminal acts.

"The law assumes that he who, while sane, puts himself voluntarily into a condition in which he knows he cannot control his actions, must take the consequences of his acts, and his intentions may be inferred." What class of inebriates is it that most frequently violates the laws of the land—and particularly those laws that relate to crimes of violence? Clearly that class that drinks the most immoderately, the most irrationally, the dipsomanical class.

Dipsomania is a mental disease. The convulsive or spasmodic drinking of the dipsomaniac is only one of the *traits* of the malady—showing that the insanity, no longer latent, has become active and raging. Magnan says: "The alcoholic excitement with which an attack of dipsomania terminates, should not be confounded with dipsomania itself, as it is a complication, not a symptom of it." Trelat also says: "Dipsomaniacs are patients who become intoxicated whenever their attack comes on." But who is the dipsomaniac? Always he is one of the neurotic constitution. He is in a state of hypnotic automatism much of the time, not only when intoxicated, but the strong presumption is, that he labors under the same disability at the very moment when he begins to consume alcohol in order to become drunken. This is inconsistent with the idea free-will, or rational volition. Drunkenness is not always, if it is ever, a factor or a part of dipsomania, but may be a consequence of it. The dipsomaniac cannot be assumed to be "sane"; and in drinking he does not "voluntarily" put himself in a condition in which he "knows" he cannot control himself. On the contrary, the dipsomaniac being insane, cannot control himself when—and before—he *begins* his ungovernable movements of intoxication. His drinking is one of a series of causes tending toward crime—the first one of which was formed in an insane mind; and for the existence of which the inebriate mind is totally irresponsible.

It is true that the uncertainties, imperfections, and necessities of human nature, make it incumbent on society to hold, within certain limits, even the insane responsible for criminal acts. Sometimes the presumed knowledge of right and wrong, abstractly, is made the test; or, whether the insane criminal knew that a particular act "was wrong," may be chosen to determine the measure of his responsibility. Nevertheless the assigned limits of insane responsibility are narrow, and often difficult to establish. It is probable that true dipsomania may sometimes be of such moderate intensity that it should not be excused from accountability for criminal deeds. Again, the mental disease may be more severe, and grave *doubts* may arise as to the rightfulness of holding it responsible for inebriate misconduct. But there are instances wherein the violence of dipsomanical insanity is superlative; and there can be no question as to the injustice of exacting responsibility for its conduct. And now the scene of strife is reached. To distinguish accurately the truly responsible, the doubtful, and the wholly irresponsible among dipsomaniacs themselves, is the work in hand. In view of the facts of dipsomania, it seems unjust and untrue to declare that *drunkenness is no defence for crime.* In strict accordance with the legal maxim already cited, dipsomania does, in all cases, present a good *prima facie* defence for criminality. The reasonable mind, the sober mind of the dipsomaniac has nothing to do in deciding upon the probabilities of intoxication; for the intoxication of dipsomania is only of a series of more or less

insane movements, begun and carried on under the forceful suggestions of mental disease. As long as the insanity is latent there is no drunkenness. The crave for drink is, in the dipsomaniac, the outcome of disease, and of unmanageable nervous distress.

The powers of mind are overcome and dominated by a peculiar form of insanity; and the will, in all such contingencies, is latent, or powerless. It must be borne in mind that the question here is not of the actual commission of crime, but that it relates to the voluntary establishment of the criminal propensity through the act of drinking.

Similar considerations apply to the character of criminal responsibility in the *habitual* drunkard. In him, incurable physical degenerations have impaired the integrity of important organs. Structural degradations of the gravest import affect perhaps, the liver, or kidneys, or brain. These may serve as centres of irritation to the entire nervous organism; and to allay this, a crave for the lethal effects of alcohol may become overmastering. Here is the incentive to drink till the full alcoholic influence is established. Degenerations within the brain materially interfere with sound judgment and rational discrimination. Here is incapacity to reason on the wisdom and the moral nature of conduct. Will, too, is inefficient and helpless, because the diseased appetites and impulses of the animal being are stronger than the determination of rational choice—and they rule the life while reason slumbers. The rigid responsibility demanded for so-called alcoholic crime should be somewhat mitigated in view of the fact that alcohol *alone*, is rather infrequently the exciting cause of criminality. Recent intoxication is generally agreeable. The mind is elated and happy. It is mainly after prolonged inebriation that the surly and truculent disposition, often attributed to simple drunkenness, appears, Then it is that strange poisons other than alcohol, have become present in the circulation. It is then that carbonic acid, urea, and other poisons not alcoholic oppress the brain, and force the mind into vicious thoughts and incentives. Under circumstances of this kind, alcohol should not be charged with the sole agency in the formation of the criminal nature; it is only one of many.

When the material instruments of the mental and moral powers are, for a protracted season, inhibited in function by the anæsthetic property of alcohol, great disturbances must ensue in the manifestations of mind and morals. Anæsthesia withdraws the nervous centres from spontaneous activity and compels the mind to assume that inferior plane of exhibition, which is merely imitative, habitual, automatic. It is impossible for a mind in which the sense of personality is wavering or destroyed to so establish its own relations with morality as to be capable of distinguishing accurately between right and wrong. To perceive what is right requires alertness and the intellectual power of clear discrimination. To recognize wrong requires the same mental properties, and also a sensitive condition of the moral faculties—which is quite inconsistent with the torpor imposed by alcoholic anæsthesia. The questions often propounded in courts of law respecting the moral capacity of criminals are in substances these: "Could the man distinguish between right and wrong? Did he know when he committed the act, that he was doing wrong?" These questions embody what the courts in England and America insist shall be a real test of legal responsibility for crime. But the power of discriminating between the fine shades of the moral qualities must be weakened when consciousness is defective; and it must be defective in some degree in every grade of anæsthesia. The law recognizes the fact that the man drunk is insane. There is actually, and founded upon the incontrollability of the mind in drunkenness, a remarkable legal inference, to the effect that *drunkenness is no defence for crime.* True, this has the appearance of a strange inconsistency; for the law also declares that "where there is insanity, that can be no crime." The legal conclusion respecting responsibility for inebriate crime involves an assumption that may be disputed. "The law has settled that a drunken intent is just as guilty as a sober one." This may be settled as law, but it is not settled as fact. There is no pretence that the law has proven the equality, or even the similarity, of a drunken and a sober intent.

The perfect mind cannot conceive of itself as being insane. The drunkard does not believe that he cannot control his action when drunk—although he cannot. He

knows nothing of hypnotism, nor of invading poisons, unexpected and unknown. The sober *ego* is wholly different from the drunken *ego*. The body is the same, but the minds are two. A sane mind may speak for another mind also sane; their faculties are on the same plane of consciousness, by reason of a similar presentation of surroundings. But a sober mind cannot speak for itself as though drunken. The differing states of the mind cause it to act as two; and they can no more explain the motives and interpret the movements of each other, than a sound mind in one person can interpret the impulses of an unsound mind in some other person.

Respecting the criminal responsibility of the man who drinks from mere idleness and without any driving, neurotic stress, and who is free from congenital and from constitutional defects—the latter arising from disease or injury—and who is free from the physical degenerations of habitual drunkenness, no doubt the rules of accountability should be strict. But even in such instance, principles of responsibility should not be "lumped" or generalized. The effect of alcohol is so modified by special nervous sensibilities and peculiarities, that it is the right of every individual guilty of inebriate crime, to have his trial made a *special* one. He is entitled to a full inquiry respecting the facts that pertain to himself alone.

THE LIBRARY TABLE.

Hygienic Measures in Relation to Infectious Diseases. Comprising in Condensed Form Information as to the Cause and Mode of Spreading of Certain Diseases, the Preventive Measures that should be resorted to, Isolation, Disinfection, etc. By George F. Nuttall, M. D., Ph. D. New York: G. B. Putnam's Sons, 1893; 112 pp. $1.50.

The author first gives a general discussion on the various methods of disinfection, by means of fire, dry heat, steam, chemicals etc., together with precautions to be followed by the physician, the nurse, care of the sick room, etc., and then describes the methods as applied to each one of 31 diseases. The plan of the work will be best seen if we take a specific example.

IV DIPHTHERIA.

CAUSE: Bacillus diphtheria; obligatory parasite.

"The infection is spread through the bacilli in the sputa, false membrane, and secretions of the various diseased mucous membranes. The bacilli are probably present at times in the stools. Physicians and nurses are particularly exposed to the danger of the infection when swabbing the throats of patients, through the coughing of mucous and flakes of membrane into their faces. Lesions of the mucous membranes where no susceptibility exists predispose to infection. The diphtheria of pigeons, calves, pigs, (not determined in the case of cats) is not to be feared as a source of human diphtheria, the diseases being due to different specific agents.

As the bacilli resist drying they may be scattered about in the form of dust. In thin layers the bacilli withstand drying for fourteen days, whilst in pieces of membrane, clothing, particularly in dark, damp, and cold places, they may retain their virulance for four to seven months. A temperature of 58° C. (136° F.) kills them in ten minutes. They apparantly die in a few days in putrifying substances. The bacilli multiply at 18° C. (64° F.), and milk being an excellent medium for their growth, the milk of dairies in a vicinity where the disease prevails may be a carrier of the infection and promote the development of the infectious organism.

PREVENTIVE MEASURES

Complete isolation of the patient is necessary as long as the slightest trace of the membrane is present, and for sometime after it disappears. Children should be kept from attending school at least four weeks after the disease has disappeared. Where the disease prevails, Lœffler maintains the importance of keeping the mouths, noses, and throats of healthy children clean, using for this purpose an aromatic or other wash every three or four hours; sublimate 1 to 10,000 or 15,000; cyanide of mercury, 1 to 10,000; chloroform water, etc. For the patients he recommends a gargle every two to three hours of the nature recommended above, together with a stronger one used at longer intervals; namely, sublimate 1 to 1,000; 3 per cent. carbolic acid in 30 per cent. alcohol; or equal parts turpentine and alcohol containing 2 per cent. carbolic acid—Virulent bacilli could not be found after a few days when this treatment was followed, whereas they are to be found usually after three weeks when the ordinary treatment is pursued. Special precautions should be taken when using poisonous solutions in the treatment of children.

DISINFECTION.

At the end of the book is found an account of the methods of surgical disinfection, preparation of the patient, of the operator, dressings, etc., followed in the Johns Hopkins Hospital.

There are few men in the country who have had the theoretical training and practical experience in this line of study, which Dr. Nuttall has had, in the laboratories and hospitals of Europe and America, and who can place so much information upon the subject of disinfection, etc., in so short a space and in so few words as is done in this short book. There is really no book which covers exactly the same ground which this book does in so concise a manner and without lengthy theoretical discussions.

A Treatise on Diseases of the Rectum, Anus, and Sigmoid Flexure. Joseph M. Matthews, M. D. With six chromo lithographs and numerous illustrations; Handsomely printed and bound; pp. 537. New York: D. Appleton & Co. Sold only by subscription.

The title of this book, and the author's name, are almost sufficient introduction to the public.

There are many books. Some should never have been written, but it would be well if we had more such practical and thoroughly valuable works, as the one under consideration. Prof. Matthews is one of the able surgeons of America who has devoted his time and study to diseases of the rectum. He has reached success and eminence.

This work illustrates the radical changes that surgery has undergone more fully than any other that we have seen. The author gives his opinions in a most positive and decided way, dealing exclusively with the present. In addition to the regular subject matters of works of this class, the author has introduced many new subjects, viz: Diseases of the Sigmoid Flexure; antisepsis in rectal surgery, etc.

Among the many good things that commend the book, we notice the sound advice on diagnosis. "I believe that the most important thing connected with medicine or surgery, is a correct diagnosis of disease."

Dr. Mathews strongly insists on a thorough examination of the patient who complains of rectal trouble. Without this, a correct diagnosis cannot be made, and without a full knowledge of the conditions, treatment cannot be pursued intelligently. The chapter devoted to the diagnosis and treatment of constipation is exhaustive, clean and original, showing the results and experience of a observant mind. The plates and illustrations are clear and accurate. The work throughout is a classical presentation of a varied personal experience.

While it should be thoroughly appreciated by the specialist, it should particularly commend itself to the general practitioner.

The style and artistic work of the book are characteristic of the well known firm of Appleton & Co.

Materia Medica, Pharmacy, Pharmacology and Therapeutics. By W. Hale White, M. D., F. R. C. P., Physician to, and lecturer on Materia Medica and Therapeutics, at Guy's Hospital, London; Examiner in Materia Medica to the Conjoint Board of England; Author of a Text-book of General Therapeutics. Edited by Reynold W. Wilcox, M. A., M. D., LL. D., Professor of Clinical Medicine at the New York Post-Graduate Medical School and Hospital; Assistant Visiting Physician to Bellevue Hospital; Fellow of the American, and of the New York Academy of Medicine, etc. 8vo, 607 pages. Cloth, $3.00. Publishers: P. Blakiston, Son & Co., 1012 Walnut Street, Philadelphia.

The text is well arranged, the definitions are comprehensive and statedin terse language, while the divisions are clearly drawn. The appendix of non-pharmacopeal remedies is an useful addition; all the better known new remedies are described. In arrangement, the work is somewhat like the well known works of Potter and Wood. The art of prescription writing receives attention; pharmacology is very fully considered and greatly adds to the value of the work.

A busy physician has no time to go into deep researches. What he wants is fact, and this is what we see in the book before us.

A Manual of the Practice of Medicine. Prepared especially for students, by A. A. Stevens, A. M., M. D. Instructor of Physical Diagnosis in the University of Pennsylvania, etc. Illustrated. Philadelphia: W. B. Saunders, 1892. Small 8vo. Pp. 501. Price, $2.50.

An examination of this book shows it to be a work that is useful, not only from its own merits but it also presents in condensed form the views of many authorities on the subject.

The author has done his work in a thorough manner. Especially is this true when we note how he dwells on symptomology, and the relations of various symptoms to each other. The treatment given, is brief, yet in accordance with the accepted method of today. The definitions are clear, concise and exact while the pathology and etiology are equally lucid.

Yet it is to be remembered that works of this class should not prevent the student from referring to more comprehensive authorities. As collateral reading we know of none better than the book before us.

CURRENT LITERATURE REVIEWED.

AMERICAN JOURNAL OF MEDICAL SCIENCES.

The January number contains the following articles:—"The Albuminuria and the Bright's Disease of Uric Acid and of Oxaluria."

Dr. DaCosta discusses those cases of Bright's disease originating in excessive uric acid formation or in oxaluria, reviewing the symptoms of a malady in which digestive disorder occurs, and in which the disturbed nutrition manifests itself in the urine, chiefly by the high specific gravity, the urates and the presence of albumin and casts that are commonly thought to indicate Bright's disease. He remarks that dyspeptic symptoms are rarely absent, though they may be very slight. The circulation is prone to be irregular, sometimes rapid, sometimes slow. Rigidity of arteries, or even tension, which is said to belong to the uric acid diathesis as well as to the contracted kidney, he has rarely noted. The hypertrophies and other cardiac lesions of Bright's

disease are absent, as are dropsy and eye lesions. A symptom worthy of note is the slight rise of temperature in the afternoon. The characters of the urine are very significant. There is the high specific gravity in a urine that is about the normal amount, or, a little scantier than normal. The urine, on standing, deposits urates, sometimes even uric acid, very often mucous. Crystals of oxalate of calcium may take the place of the urates or alternate with them. The total solids are increased. The amount of albumin is generally small, varies much with the time of day, and is mostly in the morning urine or that voided after breakfast. Casts are scanty or altogether absent. In character they are hyaline or epithelial, rarely markedly granular, never fatty.

The main difficulty of diagnosis is to distinguish between beginning contracted kidney and this affection. In advanced cases there is no difficulty. The doctor believes that the instances of diatetic albuminuria reported are in reality cases of this affection, as are also those cases where the albumin appears after severe exertion. The form of albuminuria under consideration may be met with at any age. It is rare among children and old persons. It is common in growing boys. As is Bright's disease it is much more common in the male.

The prognosis is favorable, though the cases may be of long duration, with occasional reappearance of albumin in the urine. Yet, from very long continuance of the disorder, fibroid changes may take place and interstitial nephritis result.

The pathological state is essentially a congestion of the kidney, with—should the hyperæmia persist—slight local inflammatory changes in the vascular cortex from the irritating effects of excreting increased amounts of ill-formed or broken-down tissue, in the shape of urea, urates, or, these imperfectly oxidized, as oxalates.

The treatment must not be that of Bright's disease, as commonly understood, but largely that of the underlying state, a state that we are familiar with as lithæmia, or as oxaluria. The labor of the kidneys must be lessened, as in Bright's disease, by close attention to diet. Green vegetables and fruits are freely allowed; tea, coffee, and cocoa are permitted, if sweetened but slightly. The white meat of poultry and game may be moderately taken, but the meats containing much nitrogen are forbidden. Milk has not been found especially useful. Sugars, and those vegetables containing sugar, are to be avoided. As in all forms of albuminuria, it is important to keep the kidneys flushed out by the use of pure water or the various diuretic waters. Alcoholic drinks ought to be avoided. Bathing is clearly indicated, and of the good results of moderate exercise in the open air the reporter has seen many striking examples. Among medicines, laxatives are very important. A course of muriate of ammonia, or, from time to time, of iron, is recommended. In the cases with oxalates, nitro-muriatic acid remains a standard remedy. We must not overlook the heart, and may have to meet any irregularity it exhibits from the heavy work thrown on it, by the use of digitalis and strychnia.

"Tenotomy by the Old Method."

In this paper Frederick Treves forcibly presents the claims of the open method of performing tenotomy; as by this means the operator can be certain that the proper constricting bands have been severed. The operation was abandoned because an open wound was a terror to the surgeon, a condition of things that has happily ceased under modern antiseptic methods. If a tendon can be easily and certainly divided through a small skin puncture, as the tendo Achillis, then there can be no reason for employing a larger incision. On the other hand, if the position of the tendon or band be such that its subcutaneous division is attended with the very least uncertainty, then it should be freely exposed by turning back a suitable flap of skin.

"Tuberculous Pericarditis."

Prof. Osler writes:—Tuberculosis follows hard on rheumatic fever as a cause of pericarditis. Tuberculous pericarditis is not limited to any age, and is due, in a majority of instances, to infection of the membrane from caseous mediastinal glands. The disease may be confined to these glands and to the pericardium. A second, less common, mode is from the pleura or from the lung, and, lastly, there are instances in which the pericardium appears to be involved with the pleura and peritoneum in a general tuberculosis of the serous membranes.

Morbid Anatomy.—Practically there are two groups of cases: those with firm adhesions between the pericardial layers, usually, with great thickening; and those with recent exudation, fibrinous, sero-fibrinous, hæmorrhagic, or purulent. The cases with adhesions are most numerous. Both layers are, as a rule, uniformly thickened. In other cases the process is more local, and the synechia may be limited to the front of the heart, leaving large portions of the base and of the left auricle free. There is enlargement of the heart, which may reach an extreme grade. In the cases with effusion there may be a simple plastic exudate, similar to that in rheumatic pericarditis, with little, or no effusion, and with scarcely any thickening of the membrane, the eruption of miliary tubercles, alone, indicating the nature of the process. More commonly there is extensive sero-fibrinous exudate consisting of flakes of lymph, and a turbid serum. In some cases, the exudate is hæmorrhagic, and the membranes here may be deeply engorged, and hæmorrhagic foci be seen in them. The color of the effusion may be bright red, but is more commonly a reddish-brown or chocolate.

In the clinical history, four groups of cases may be recognized:

First. Latent tuberculous pericarditis; the disease being discovered accidentally.

Second. With symptoms of cardiac insufficiency following the dilatation and hyper-

trophy consequent upon chronic adhesive pericarditis. The clinical features are really those of cardiac dropsy.

Third. Acute tuberculosis. The clinical picture may be that of an acute tuberculosis, either general or with cerebro-spinal manifestations.

Fourth. Cases with symptoms of acute pericarditis. This group, the most important in many respects, includes cases in which the pericarditis is acute and accompanied with more or less exudate of a sero-fibrinous, hæmorrhagic, or purulent natnre. Here, too, the process may be latent.

The diagnosis of tuberculosis pericarditis is extremely uncertain. In the large group of cases in which the membranes are thickened and united, the difficulties are those which pertain to the recognition of adherent pericardium. If there has been no history of rheumatism, and, if there are indications elsewhere, of tuberculosis, a probable diagnosis can be made. In the cases that set in as acute pericarditis, unless there are evidences of tuberculosis in other parts, a diagnosis can rarely be made.

Treatment. It is not improbable that tuberculosis of the pericardium, may, like that of the peritoneum, recover completely. A case, that has set in acutely, must be dealt with as any other form of pericarditis, the indications being to limit the intensity of the inflammation and to prevent the evil consequences of the presence of a large amount of fluid in the sac. We have no medicinal agents at our command which have any positive influence in controlling the ordinary inflammation of serous membranes. There is one measure on the utility of which we may rely, namely the ice-bag, applied continuously over the præcordium. It allays the pain when present, and appears to check the tendency to effusion; while under its use an exudate may be absorbed with rapidity. It is much to be preferred to blisters or the thermo-cautery. Where patients complain of the cold, Leiter's coil may be used with running water of the proper temperature. When the effusion reaches a certain grade, and the pulse is irregular and feeble, the color becoming bad, the respirations hurried, paracentesis should be performed, or, if necessary, the sac freely incised and drained.

"The Tampon in Menorrhagia" by William T. Lusk, M. D., of New York.

In this paper he urges the claims of the tampon in those cases of menorrhagia in which there is no definable cause for the bleeding and in which the curetta, uterine drainage and internal remedies fail to give relief. The method of applying the tampon receives due attention.

"Methods and Results in Cases of Tubercular Disease, Aneurism, Ununited Fractures, and Head Injuries," by J. William White, M. D.

The cases are for the most part taken from the last eighteen months service of Dr. White at the University Hospital, and include Tubercular Arthritis, Tubercular Adenitis, r eated by the removal of the glands and by the injection of an iodoform emulsion. The report also contains an account of five cases of Aneurism which were treated by compression in some cases and ligation in others. The paper also discusses excision of the elbow, of which eight were performed. One case of Lupus of the face was cured by Tuberculin. Delayed union and ununited fractures, with the various operations resorted to in their treatment are discussed, together with the several cases. Head injuries—All depressed fractures whether simple or compound are elevated. The report includes eight cases of trephining, of which six recovered.

The paper is to be continued in the next issue.

"The Cholera of 1892 in New York: its Prophylaxis and Treatment," by Reynold W. Wilcox.

"History of the Recent Outbreak of Epidermic Cholera in New York."

"The Bacteriological Examination of the recent cases of Epidemic Cholera in the City of New York," by Edward K. Dunham.

In these three papers the recent outbreak of Cholera is reviewed in its different lights and the measures taken for its prevention and treatment are fully discussed. The report on the bacteriological examination of the discharges is illustrated by wood-cuts of the various appearances of the cultures at the different stages of development.

UNIVERSITY MEDICAL MAGAZINE.

The most important practical article in December's issue, is the one offered by Dr. Traill Green, "Ergot and the Abstetric Forceps." Dr. William Carpenter's paper "A Clinical Study of the Gonococcus" received the prize offered for the best clinical study of a surgical subject by a member of the graduating class, University of Pennsylvania, 1892. The question raised and the point sustained, by careful microscopical and laboratory work, is— as to whether blenorrhagia is always associated with an individual microorganism, which either by its form, grouping, color, reaction, method of growth, or inoculation, or by all these characteristics combined, is so distinctly different from all other bacteria, that with absolute certainity it can be regarded as the cause of the disease, and that when discovered it constitutes an absolute proof of the presence of true gonorrhea." Dr. Wood in a "Memoranda" entitled "Notes on Quinine Idiosyncrasies" calls attention to two remarkable cases of cinchonism.

N. Y. JOURNAL OF GYNECOLOGY AND OBSTETICS.

An uncommonly good paper, is a translation of Professors Crede and Leopald's treatise, "The Obstetric Examination," by Dr. Edgar. The subject is well illustrated, and considered under two heads, external and internal examination.

Dr. Allen Thomas gives a brief statistical report of and remarks upon a period of Obstetrical Service at The New York Emigrant Hospital. Several other articles of minor importance complete the December issue.

PERISCOPE.

THERAPEUTICS.

Salol has at last been obtained in solution as a pleasant, palatable liquid. Elixir of salol as described, is a solution by mechanical means only, of 5 grs. of salol in each dessert-spoonful making a palatable liquid, the advantages of which can be clearly seen in the fact that it renders administration of salol very easy, especially to children and those who can not take powders or pills.—Medical Era.

Paraldehyde.

This remedy is considered in a paper in "Notes on New Remedies." Summing up in the briefest possible form what has been said about the properties of paraldehyde, it is found:

1. That it is an efficient and safe hypnotic.
2. That it is sometimes effective where chloral hydrate fails.
3. That it is free from injurious action on the vital functions.
4. That it even facilitates the digestion of fibrin.
5. That in proper dosage it may be prescribed without apprehension.
6. That it is conveniently and agreeably given in mixture form.

Evidences of no little weight of the general usefulness of paraldehyde is afforded by the fact that it has been adopted into the German, Italian and the British Pharmacopeias.

It should also be reorded that, in common with many other sedatives, paraldehyde also has been recommended as an antidote to strychnine poisoning.—Med. Rev.

Some Internal Uses of Chloroform.

We find the following in the Memphis "Medical Monthly:" In gastralgia with dilatation of the stomach, in the treatment of nervous vomiting, and of the vomiting of pregnacy, chloroform water in the dose of a small teaspoonful every half hour or hour, is a very useful remedy.

In false croup, employed in the proportion of one to ten drops in an ounce of water, to which is added a little glycerine; dose, one teaspoonful every half hour; the effect is a very happy one.

In ulcer of the stomach, small doses of chloroform given internally will often remove the pain and stop vomiting.

In the treatment of whooping cough, three to six drop doses of chloroform in syrup will bring about very good results.

In the albuminuria and anasarca of pregnacy, chloroform in twelve to twenty drop doses in sweetened water causes a rapid diminution in the albumin and the disappearance of the anasarca.—Med. Rev.

Use of Ipecacuanha in Uterine Inertia.

Drapes says this remedy in simple atony of the uterus is a powerful agent in producing uterine contraction during the first and second stages of labor. In general, two or three doses of from ten to fifteen drops of the wine of ipecacuanha, given at intervals of ten minutes, produce in a short time marked activity of uterine action and a rapid birth. It is much better than ergot, as it does not produce tetanic contraction, but only induces normal and regular expulsive efforts.—Med. Rev.

Who Owns the Prescription?

This has been answered by a Cincinnati court as follows (Meyer Bro's Druggist):

"A druggist is under no obligation to furnish a copy nor to permit any one to make a copy of prescriptions. When he has compounded a drug and delivered it to the proper party, the paper upon which the prescription is written becomes his. Druggists keep prescriptions for their own protection. If, as the plaintiff testified, defendant had agreed to furnish plaintiff with a copy whenever he called for it, that agreement was gratuitous and without consideration and therefore void."

This is in accord with other decisions which we have published.

How would it do for druggists to print this decision on the back of their prescription blanks?—Med. Rev.

Aristol.

Nearly all drugs, whether or not originally intended for external use, have been applied at one time or another, to local, exterior traumatisms in the once current belief that remedies that are good within should be good without. The conspicuous failure of the many attempts to obtain a perfect dressing for suppurative conditions which should be equally good for accidental or operative injuries constitutes an interesting section in the history of surgery. Even the latter surgical dressings have, for the most part, proved failures in some essential quality. Some of them possessed an unspeakable odor, others were toxic, many were difficult of application, and a further series, though admirably adapted to a particular surgical requirement, failed as complete surgical dressings. The promptness, for instance, with which Aristol was adopted by practitioners demonstrated the great, existing need of an adherent, stimulating, safe and effective cicatrisant. The evidence thus far appears to demonstrate that Aristol has not disappointed the profession in any of these particulars.—Miss. Med. Monthly.

MEDICINE.

Treatment of Catarrhal Sore Throat.

Dr. Carter mentions a number of remedies for this class of cases which should be selected according to the variety and degree of inflammation present, and the condition and idiosyncracies of the patient. Hot wine gargles are recommended by some. Menthol, being an antiseptic and local anodyne, is useful, contracting the capillaries and checking secretions. In dry, cold weather, when the mucous membrane is parting with its moisture, which is nature's covering cloud, treatment with vaseline spray acts well. Cream and ice are particularly valuable in children who cannot use spray or gargle. The essential oils, by spray or nebulization, are also valuable in these dry forms. Solutions of chlorate of potash and permanganate of potash and other astringents are useful in this form of sore throat, when the secretion is profuse. They may be used either as spray or gargle. Where the secretions are too albuminous, or where there is a tendency to the formation of penlicles on the tonsils, a spray of peroxide of hydrogen is indicated. Yerba reuma, by atomization, is sometimes very valuable. In nearly all cases where there is general febrile disturbance, aconite and belladonna are invaluable.—Jour. of Am. Med. Asso.

Tuberculous Ulcers of the Stomach.

Dr. J. H. Musser (Medical Press and Circular) says:

1. Tuberculous ulceration of the stomach is rare.

2. It occurs more frequently in childern.

3. It is never primary.

4. Gastric infection is probably due to the voluntary or involuntary swallowing of sputum.

5. The presence of the bacillus tuberculosis is the only positive proof of the nature of the ulceration.

6. The anatomical peculiarities of this form of ulceration include the following:

The seat of the ulcer is in the lesser curvature, although it may be found in any position.

More than one ulcer is usually seen.

The ulcers are large and irregular.

Miliary tubercles on the floor of the ulcer, in the submucous coat, are seen.

The ulcers are near vessels, and the results of vascular ulceration are found.

Small caseating masses are seen in the ulcer or at a portion of the periphery. Similar collections are found in the territory adjacent to the ulcer, in the submucous coat.

The peritoneum is studded with miliary tubercle very often.

Neighboring lymphatics are often involved.

7. In the large majority of cases, there were no symptoms during life.

8. Sudden hæmorrhage is a frequent symptom and cause of death; it has been particularly noted in children.

9. Epigastric pains and vomiting may occur.

10. The presence of gastric symptoms of this kind, occuring in the course of tuberculosis, is significant of possible ulceration.

11. In view of the fact that the swallowing of sputum is posibly dangerous, expectoration should be insisted upon in adults and its method taught to children.—Amer. Lan.

NEWS AND MISCELLANY.

Dr. Robert Crawford, of Cooperstown, Venango Co., Pa., died at his home on Chrismas morning after an illness of theee or four days. Dr. Crawford has been in active practice for over fifty years; was a very able man and stood among the leaders in the profession for a generation.

ARMY AND NAVY.

FROM DECEMBER 18, 1892, TO DECEMBER 31, 1892.

Leave of absence for fifteen days, to take effect on or about January 11, 1893, is hereby granted Captain W. B. Banister, Assistant Surgeon, U. S. Army.

1st Lieut. Frank T. Meriwether, Assistant Surgeon, is relieved from further duty at Fort Adams, Rhode Island, and assigned to duty at Madison Barracks, New York.

The Leave of absence granted Captain Louis W. Crampton, Assistant Surgeon, U. S. Army, is extended three (3) months.

By direction of the Secretary of War. two months ordinary leave of absence, is granted Captain Marcus E. Taylor, Assistant Surgeon, U. S. Army, to take effect upon the expiration of his present sick leave.

1st. Lieut. James D. Glennan, Assistant Surgeon, U. S. Army, will upon his arrival at his station (Fort Sill. Okla. Ty.) from leave of absence, proceed immediately to San Antonia, Texas, and report in person to the commanding general Dep't. of Texas, for temporary duty in the field with proofs operating on the Mexican border.

The leave of absence for seven days granted 1st Lieut. Frank T. Meriwether, Assistant Surgeon, U. S. Army, is hereby extended ten days.

1st Lieut. Benjamin S. Ten Eyck, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Leavenworth, Kansas, and will proceed at once to San Antonia, Texas, and report to the commanding General Department of Texas for duty with the troop now in the field.

Pharmaceutical Specialties

ARISTOL Antiseptic: Cicatrisant.

EUROPHEN Iodoform Substitute: Antisyphilitic.

SULFONAL-BAYER Hypnotic: Sedative.

PHENACETINE-BAYER Antipyretic: Analgesic.

PHENACETINE-BAYER is a true and distinct organic derivative. It is indicated in influenza (*la grippe*); in all fevers, with or without pain; in rheumatism and neuralgia; and in phthisis and pertussis. It acts promptly and is both safe and effective. Supplied in ounces, tablets and pills.

EUROPHEN, as a substitute for iodoform, is winning an enviable place in therapeutics. It has a special value in specific lesions, while as a surgical dressing in ulcerations, open wounds, and septic conditions of the cavities, it has given excellent results. Supplied in ounces.

SULFONAL-BAYER is indicated in all the insomnias and in the cerebral disturbances of insanity. It is a pure hypnotic, a safe and effective remedy, and it does not give rise to a drug habit. For the correct method of administration *see pamphlet*. Supplied in ounces, tablets and pills.

ARISTOL is widely esteemed by physicians for the excellent results it has given in the treatment of all external traumatisms; in cavital lesions, and in many of the dermatoses. As a surgical application, it is safe, inodorous and non-toxic. Supplied in ounces.

EUROPHEN-ARISTOL, a preparation consisting of equal parts of each medicament, is also supplied in ounces.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Vaccine Matter.

For the accommodation of our Subscribers, we will supply both Bovine and Humanized Vaccine Virus.

Guaranteed to be fresh and in every respect first-class.

PRICES:

Bovine Crusts,	**$1.50 each.**
Bovine Points or Quills,	**1.00 a dozen.**
Humanized Crusts,	**1.00, small.**
Humanized Crusts,	**2.00, large.**

Nothing less than half dozen sold at these prices.

The Humanized Crusts are warranted to be from typical cases, and in every instance from healthy children, with unquestionable family histories.

Please accompany the Order with the Money.

OBJECT LESSONS IN GYNECOLOGY.

W. H. LINK, Petersburg, Ind.

IV. TIMIDITY AMONG COUNTRY DOCTORS.

There is a great deal said about the timidity of the country doctor, and our city cousins often marvel at our hesitation and no doubt feel sorry for us without reflecting on our environments or understanding the conditions which either favor or hinder successful work. Among us there is no lack of boldness except when we lack exact information. We are far away from dissecting rooms, and our anatomy consists of what we learned while at school with what we can acquire by occasional references to Gray or some other text-book. We remember a great deal of theoretical teaching which blessed us in student days, and now and then recall a practical lesson which some one of our teachers gave, that serves to guide us through a doubt or difficulty. We are all-round specialists. To-day doing an abdominal section, to-night a high-forceps delivery or a podalic version, to-morrow amputating a toe, removing a pterygium, trephining for fracture, or pulling a tooth, then hurrying away to a case of typhoid fever or cholera infantum. Being well-grounded in the branches of medicine necessary to do all these varieties of work with credit to ourselves and satisfaction to our patients, we must, of necessity, be good in all lines and exact and thorough in none. Our obstetrics is better than that of the city surgeon's, but our surgery not so good. Our surgery is better than that of of our city friend who devotes himself to obstetrics, but our treatment of the eye is not up with that of him who treats the eye alone. Our general practice in systemic diseases is not equal to that of Pepper or DaCosta, but we can reduce a dislocation or adjust a fracture better than either of them. There is a certain boldness, too, which prevails among hospital physicians and surgeons, because of the shortness of the time during which professional relations exist between them and their patients, and the lack of severe personal responsibility which of necessity obtains among them. Of course the hospital physicians or surgeons are responsible to their conscience, and we believe they have as high a standard of rectitude as any set of men in the world; but if a bad result follow their work, or they decide to try a new method or a new line of treatment, they do not have to explain to the friends of the patients and defend it from the harsh criticisms of envious rivals.

We in country practice while losing a patient are always losing a personal friend, and not seldom alienating a whole family. This fact often makes us appear to hesitate where our friend of the hospital staff would cut the Gordian Knot with his scalpel and save a life, which, at the worst, would undergo no more risk from the operation than from the effects of the disease itself. The bread and butter argument creeps into our lives when we try to be most unselfish and we hesitate to take a course not backed by authority, because we get the moral support of our brethren, hence the support of public

opinion, only by treading the beaten path. The man in the city being more a law unto himself, and having charge of those who are looked after by the charity of others, is expected, occasionally, to strike out new roads for the benefit of mankind and for the purpose of settling doubts, or establishing methods or remedies that meet new demands. The country doctor is to a large extent a slave to text-books. What exists between the leaves of conceded authorities is to him the garnered wisdom of ages; and the cautions and exceptions addressed to him by his well-thumbed authors, make as strong an impression as the rules and principles which they lay down for his general guidance. "It is the unexpected which always happens" say the French, and when one is in doubt it is the unexpected which he fears. Hence, text-books which ought to hold up his tired hands while the battle with disease or accident is being fought are but wavering supports, albeit the best in reach. He can not stray very far from the accepted teachings of his books, for in case of a bad result, neither expert, judge nor jury will sustain him. Medical journals and medical societies can not lift him from the slough of text-book lore, because his county society meets very seldom, and the bad state of the roads, if no other reason, keeps him at home one-half the year. Journals may keep him alive to what is going on at the great medical centres, but the new ideas put forth in them must be tried many times by others ere he ventures to try them in his practice and upon his patients.

The great names of the past are cherished by the country doctor with a reverence, which, if it did not carry with it too great a reverence alike for their teachings, might be commendable. A man, however great, must often err, and thus it is that "The evil men do lives after them," even if the good be not *all* "interred with their bones!"

The country doctor, in his daily work, never comes from under the shadow of his early teacher's influence. Of course, the exigencies of practice soon show him that they lack the infallibility with which his student imagination invested them. Yet their methods and precepts are remembered and often followed long after he has discovered that many of them were very ordinary men who had stepped into the place of teacher, not by reason of any inherent quality of preëminent fitness for the place, but through some adventitious circumstance or attribute, foreign alike to professional character, and not necessarily coexistent with great professional attainments. As the faculties of none of our colleges contain more than two or three truly able teachers, it follows as a matter of course, that the vast majority of the teaching is done by a host of mediocres, who echo alike the errors and the truths of the past, mixing a great deal of what must be unlearned with what is known to be true, and tarnishing the brilliant things of others with the leaden hue of their own stunted minds. All this has a disastrous effect on those men who must go out to the world relying upon precepts from such a source for guidance.

The modesty of the practitioner remote from medical centres adds to his timidity from other causes. Feeling his lack of exact knowledge, and greatly magnifying the advantage of his more favorably situated brethren, he often gives nature a longer trial and a better chance than she would have in a city or larger town. This fact as often redounds to the benefit of the patient as a more active policy; especially, if that policy has no better reason behind it than enthusiastic boldness and strong self-confidence. If any one asserts his superiority, the country doctor not knowing how little, *how very little* difference there is between the great lights in medicine and the more humble of its followers, rapidly concedes all that others claim for themselves; and, knowing that he cannot perform the wonders which others daily claim, takes it for granted that he can not be up to their standard, and blames his opportunities for much that is more fancied than real. He is ready at all times to confess his defects; and, on account of them, he now and then withholds his hand, because he doubts its strength and skill. He performs his alloted tasks, feeling only that his conscience does not reprove him for not being as good on every line as some of his city friends are in some one particular field of work.

The prevailing tone of both stereotyped and current medical literature has much to answer for in the matter of multiplying the doubts and increasing the hesitation of the country physician. We

are constantly warned at the threshold or end of the description or explanation of every operation or manipulation of magnitude or difficulty, that only the specially trained or skillful should undertake it; that the skill to do most things is only vouchsafed to a few of the Lord's anointed, and that it is much safer to call counsel than to undertake some delicate or dangerous piece of work until we have become specialists. In other words, we must not go near the water until we have learned to swim. This makes a fine harvest for those who have learned to swim; but it leaves us just where we began, standing on the bank shivering with dread at the water, while our patients drown before our eyes for want of that help which we ought to give.

Another cause for our timidity and backwardness is the meager pay which we receive for our best and utmost efforts. To buy the best-books and to take the highest and best class of current literature costs money, while a liberal supply of necessary instruments is to the country doctor an expenditure of almost a small fortune. Being a representative of all the specialties and the practice of medicine also, to be moderately well equipped he must have a number of instruments for each line of work and the special instruments of diagnosis and treatment that pertain to successful practice in the mere application of remedies to the cure of disease non-surgical in character. The city practitioner often gets more for the performance of one operation than the successful and skilled country doctor does for a year's work. As the gratitude of patients is in a direct ratio to the size of the fee paid, it can very readily be seen that there is small encouragement to anything like boldness in action or fullness and completeness of equipment.

Notwithstanding the truth of the foregoing, the history of medicine shows that the country doctor has at times risen to the level of the heroic, and, in the absence of sustaining counsel, by some bold act or sudden inspiration become an epoch-maker in the progress of a great and noble science. We remember with pride that the whole science of abdominal surgery owes its origin to the backwoods surgeon of Kentucky. We like to recall the fact that Baynham, another country doctor of Virginia, operated successfully for ectopic pregnancy long before the advent of Lawson Tait. It was J. Marian Sims, a country doctor of the South, who put the operation of vesico-vaginal fistula on the list of curative lesions and who revolutionised the whole practice of Gynecology.

It was a country doctor in Ohio who first made the improved Cæsarean section, sewing the uterine walls with silver wire, a procedure which, under the name of the Sænger operation, has led a great many to suppose that we owe it, like other good things, to Germany. It was Benjamin W. Dudley, another country surgeon, who made a lithotomy record so high that no man has ever yet been able to duplicate it, even though we have, by the aid of Germany, discovered a universal cause for all surgical failures—*bugs*. What a miserable man this Dudley was who went on making one lithotomy after another, curing his cases, while blissfully ignorant of the fact that everything he touched, even the very air he breathed, was literally swarming with bacteria or micrococci. Had he lived to the present time, he might, by the aid of chemical solution, have run his mortality up from four per cent. to ten or twenty per cent. In fact, by striving hard, he might have equalled some of the best German operators in piling up a mortality list.

Head Injuries with Aural Complications.

Dr. J. E. Sheppard (*Archives of Otology*) says:

1. That the division made by Dr. Buck of fractures of the temporal bone into (*a*) "fracture or disastasis of the tympanic or squamous portion, in the region of the middle ear, without implication of the pars petrosa; and (*b*) fracture of both the tympanic and petrous portions," is an entirely tenable and eminently practical one.

2. That fractures of the temporal bone without fatal consequences, and even without loss of hearing, occur more frequently than is generally believed.

3. That in all cases of suspected fracture of this part of the skull, a thorough examination (by speculum and reflected light) should be made of the external auditory canal, of the membrana tympani, and, so far as possible, of the tympanic cavity, as an aid to diagnosis and prognosis, and to obtain any indications that may exist for treatment.—*Am. Lan.*

CRIMINAL RESPONSIBILITY IN THE EARLY STAGES OF GENERAL PARALYSIS.

FRANK P. NORBURY, M. D., Jacksonville, Ill.

At no time in the history of civilization have influences so comprehensive and far-reaching been contributory to spurring men to action beyond their capacities to bear as to-day. We are "a restless nation possessed of an energy tempted to its largest uses by unsurpassed opportunities," the disastrous results of which are shown in premature decay, in that most prevalent disease, neurasthenia, with its attending miseries and in the increase of that form of mental derangement known as general paralysis of the insane. While it is true that syphilis is the basis of much of general paralysis, yet, the exciting cause, even in these cases, is over-work, brain tire and abuse of the nervous system. The American disease, neurasthenia, offers hope for recovery; the mental derangement, general paralysis, is a disease that carries its victims sooner or later, to the grave. A study of this most protean malady is of great importance to every physician, for its early recognition will often modify the progress of the disease and prevent crime by placing the patient under proper treatment.

Further, we are hopeful that with the advancement and dissemination of the clinical knowledge of this disease it will be recognized while in its functional stage and here arrested. Folsom, of Boston, has (of the American writers,) given us the most classical description of this disease, which I hear quote.

I. GENERAL PARALYSIS.

"General paralysis is clinically a primary disease, sometimes acute, but for the most part subacute and chronic in its early manifestations, with a definite recognizable anatomical basis and progressive, in which symptoms of brain failure, too slight to be remarked at their actual incipiency, are rapidly or slowly succeeded by a cerebral inco-ordination, both psychic and motor, including under the term psychic the so-called moral as well as purely intellectual attributes of the mind; a disease which in its course involves every function of the brain and may in its various phases exhibit many of the symptoms observed by the neurologist, as well as most of those known to the alienist, first impairing, then paralyzing in its steady progress all those high qualities, mental and physical, that distinguish civilized man; and finally, after the wreck of mind and body destroying life itself."

The early symptoms will concern us in this paper; they have not been very satisfactorily studied, because the attending physicians have not distinguished general paralysis from other forms of insanity and as a consequence the prodromal stage is generally passed before the alienist meets the case. The family or friends have been aware of a change in the character and disposition of the patient, but have not been alarmed, "thinking it would pass away."

But no! The case is progressive, and some day they realize that insanity exists and forthwith apply for hospital treatment, too late, however, for the benefit of the patient. Brush says it is unfortunate that the clinical features of the early symptoms of general paralysis are not more graphically defined, and attributes the cause to the lack of observation on the part of the attending physicians, who in a very few instances have recognized the disease, even after it has advanced to such a degree as to require asylum care.

The diagnosis of general paralysis is rarely made, as is evidenced in the following diagnosis taken from twenty-six cases coming under my observation during the past four years: Nervous prostration, melancholia, traumatism, la grippe, brain softening, alcoholism, morphine habit. In the majority no form of insanity is given and the cause is stated as unknown.

Folsom, of Boston, and Hughes, of St. Louis, have exhaustively studied the early symptoms of general paralysis. Folsom says the earliest signs of general paralysis are of the slightest possible brain failure. If, for instance, a strong, healthy man, in or near the prime of life, distinctly not of the nervous, neurotic or neurasthenic type, shows some loss of interest in his affairs or impaired faculty of attending to them; if the become varyingly absent-minded, heedless, indifferent, negligent, apathetic, inconsiderate, and although able to follow his routine duties, his ability to take up

new work is, no matter how little, diminished; if he can less well command mental attention and concentration, conception, perception, reflection and judgment; if there is no unwonted lack of the imitative, and if exertion causes unwonted mental and physicial fatigue; if the emotions are intensified and easily changed or excited readily from trifling causes; if the sexual instinct is not reasonably controlled; if the finer feelings are even slightly blunted; if the person in question regards with a placid apathy his own acts of indifference and irritability and their consequences, and especially if at times he sees himself in his true light and suddenly fails again to do so; if any symptoms of cerebral vasomotor disturbance are noticed, however vague or variable—then we can regard his case as one of general paralysis.

Hughes, in a personal letter to me, says: "There is undoubtedly a pre-ataxic stage of general paralysis; a hyperæmic condition when the paretic individual engages in, or is inclined to engage in, business and other ventures having few features of certainty in outcome to commend them that would enlist the active financial interest of the person about to be afflicted with paretic dementia in his normal mental state. At this stage, when self-confidence is becoming supreme, and the morbid impression of conscious capacity for success in almost any undertaking is possessing and growing intenser in the mind every day, the victim of commencing paresis may complicate his social relations as he is liable to do his business affairs, and just as he might do and does do in beginning paresis, where the inital symptoms are those of mental depression or melancholia."

Savage, of England, in a paper on the warnings of general paralysis, says: There are two forms of onset of the disease—the gradual and the sudden. In the latter, there is nothing to warn before the storm has broken. In the gradual onset there is a more or less regularly progressive degeneration of mind and body, so that the highest faculties show the first signs of change and the special attainments fail before the more general; the finer social and the finer muscular adaptations fail and changes and weaknesses in mind and body show themselves. To start with the motor side: Early fatigue is most marked, and is associated with indecision, doubt and hypochondriasis. Temporary aphasia he regards as an important symptom, and is present long before change in handwriting is noticed. This change in handwriting is specially an important symptom, and is present for a year or more before signs of general paralysis are declared. Facial expression changes, the face becomes fat. The mental and moral tone is changed; the changes of temper and character are noticed early in general paralysis. Self-feeling is exaggerated, hypochondriasis is a frequent warning, and in such cases the morbid ideas are centered in the gastro-intestinal tract. The combined motor and mental symptoms lead to a diagnosis of general paralysis.

The symptoms, as detailed by these authorities, seem striking and capable of being recognized, but careful study of the patient and painstaking interrogation of the family and friends are also necessary to define a case of general paralysis. The mental symptoms are variable, but usually this feeling of well-being prevails, characterized by excessive cordiality, boasting of power and wealth, marked by extravagance in everything undertaken. Emotions are seemingly in a balance; anger is easily and hastily aroused and as easily and hastily calmed; crying and laughing alternate quickly. Moral lapses are so frequent at this time that females are assaulted, undue exposure of the person made in public places, sexual and alcoholic excesses are common, and so frequent are the varied moral lapses that the unfortunate subject, especially if he belong to the lower class of society, becomes lodged in jail for offenses committed. His irritability and anger may lead him to murder, assaults, and trespass on the rights of others. His exalted ideas of power and authority cause consternation in assembly halls, churches and in the seats of government. Such, in brief, is an outline of the early symptoms of general paralysis; the latter stages are seen within the walls of an insane hospital, where death, sooner or later, comes to relieve the weary sufferer of the burden of life.

2. RESPONSIBILITY.

Medicine and law differ radically on the question of responsibility. Scientific medicine has been the pioneer to explore the still unsettled regions of criminality among the insane, and has satisfactorily estab-

lished principles which the legal profession must sooner or later acknowledge as scientific truths. This question of responsibility, as viewed by medicine and law is, as Judge Somerville, President of the New York Medico-Legal Society, says, "the same old fight of science against the crystallized prejudices of error and ignorance."

The law, on the other side, claiming culpability when knowledge of right and wrong exists; medicine, on the other, holding there is no criminal act when the individual cannot choose between right and wrong because of the destruction of the power of self-control. The medical test is based on the presence of disease and its abnormal results on conduct; the legal test is metaphysical and theoretical. Medical diagnosis is based on pathology and experience; the legal ignores any physical condition which does not affect the moral attributes. The law cares nothing for impulse, loss of will power or sudden change of character and conduct without motives or from childish incentives. Medicine tests scientifically by taking in the whole man; it gives a study of the individual, a comparison of his mental condition when the crime was committed, with himself at periods remote and subsequent. By so doing we permit of the only rational method of determining sanity from insanity. "We supplant tradition and fiat of statutes by the facts of clinical medicine from which we draw just conclusions." We at once recognize the importance of a study of mental diseases in order to thoroughly and adequately determine responsibility.

A physician is, by right, the proper person to conduct an examination to determine the unsoundness of mind. The familiarity with mental diseases accorded him in our State by the law, requires him to acquaint himself with these diseases in order to sustain this position. That he does not do this we are painfully aware, and because of this inattention, either through ignorance or indifference, the medical profession has been made to suffer ridicule and opprobrium from lawyers, judges and the press. So far has this gone, that it has been said that any ordinary man is able to detect any form of insanity as well as a physician.

We, in the description of general paralysis, have shown the difficulty attending the diagnosis of this form of insanity and have insisted upon prolonged observation in order that no mistake may be made. The same will apply to all forms of insanity, especially so in cases involving criminal responsibility, and we reiterate that, for the sake of justice in cases presenting the plea of insanity, where doubt exists as to insanity, observations of the case be made, and preferably by temporary commitment to an insane hospital, where the experienced superintendent and other medical officers may scientifically examine the case. The want of such methodical observation has no doubt caused many innocent to suffer and many guilty to escape. Such an examination impartially pursued will render great assistance to the courts and aid in the establishment of medical expertism upon a firm and scientific basis.

3. RESPONSIBILITY IN ITS BEARING UPON GENERAL PARALYSIS.

I am sure there are many unfortunates serving sentence to-day for crimes committed, who should be treated as sick patients and given the attention they deserve. An analysis of their crimes will show that a diseased mind prompted the act and a disorganized will power permitted its commission. The crimes, if they should so be called, of a general paralytic differ from those of the normal or criminal insane. Bevan Lewis says regarding the crimes of a general paralytic as compared to the moral insane: "In the latter the crimes indicate impulsive and uncontrollable states as the result of a lowered or defective moral sense; the normal inhibitory control is wanting and instinctive impulses rise in full activity. It is not so with the acts of a general paralytic; they are neither premeditated nor impulsive, but casual, often appearing to be unconsciously performed; even if the act appear determinate its nature and consequences are wholly obscure to the agent's mind."

And here the essential nature of these acts on the part of each subject becomes apparent; the high degree of representativeness essential for the recall of similar actions previously performed and the vivid realization of the consequences of such action in the past, is here wholly wantingless; and still less is that re-representative faculty intact, which enables him to contrast the act as viewed in its nature with certain ethical canons. The

moral lapse is therefore truly significant of a clouded intellect, an act of theft may be committed with open effrontery, no attempt at concealment being made; the most wanton outrage on public decency, the most audacious libertinism, may be committed quite oblivious to being a breach of public morals. Hughes, in his letter, says: "I would suspect and recommend surveillance for a very active business man of from 36 to 45 years of age who might be found acting in a manner different from that which, up to that time was natural to him in business or social affairs, especially if his conduct was such as might be attributed to a man under the exhilaration of drink, when it could be clearly shown that the man did not indulge in alcoholic drink at all. I am convinced that a good deal of unrecognized and irreparable harm has been done to the interests of paretics and the welfare of the families by rash procedures on the part of the former, which were unnatural to them in their thoroughly sane condition by acts (business or otherwise) committed in the hyperæmic preataxic stages of this disease."

Folsom, in a recent letter to me, says, regarding the conviction and imprisonment of general paralytics:

"I do not see how it is consistent with a reasonable sense of justice to convict a general paralytic in any stage of his disease, no matter how early, and when a man of previous good character commits a crime it seems to me that he should be placed in an insane asylum for observation, if there is any doubt as to his responsibility. I have no doubt that in the near future all of our states will have laws, as some of them now have, empowering judges to send people to insane asylums for observation in case of doubt of their sanity, and that judges will more frequently use this power."

In our State we have no such provision; in fact, our lunacy law is a failure, both to the practical commitment of the insane and the protection of their best interests. The *mittimus* on which an insane person who has committed a criminal act is admitted into the insane hospitals of this State is equal to a life sentence in cases of general paralysis. It instructs the superintendent of an insane hospital "to take the body of said defendant (the hopeless paralytic) and confine him in said hospital until he has fully and permanently recovered from his insanity,"—which is when he dies. The general paralytic is not justly committed to a hospital on such a legal paper, because, *first*, he is a sick man; *second*, he is not responsible for any criminal act whatever, and, *third*, it is oftentimes to his advantage and a pleasure to his friends to have temporary absence from the hospital, and in case of impending death, to satisfy the desire of his family or friends, it may be best to remove him to his home, which cannot be done when committed on a *mittimus*.

My conclusions are, after carefully studying the medico-legal bearings of responsibility in the early stages of general paralysis:

I. General paralysis is a plea for irresponsibility.

II. No judge is warranted in committing a general paralytic to the penitentiary.

III. It is not judicious or right to commit general paralytics to insane hospitals on a *mittimus*.

IV. When in doubt as to the existence of general paralysis it is the duty of the judge or jury to forego sentence and commit the individual to an insane hospital for observation, at least long enough to determine the existence or non-existence of general paralysis.

CLINICAL LECTURES.

INFLAMMATION; PUS; POSITIVELY AND NEGATIVELY CHEMOLACTIC SUBSTANCES.

HENRY W. CATTELL, A. M., M. D.*

Inflammation is a composite pathological process, and is the most important process with which we have to deal in the whole subject of gross morbid anatomy. There is hardly a process which starts or ends a pathological change that has not inflammation as a factor at some time or other in its course. A clear conception of this subject of inflammation, added to a full knowledge of the anatomy of the part, together with a good understanding of such conditions as infiltration and degeneration will lead you to comprehend most clearly all special pathological changes.

Changes due to irritation of the connective tissue, is a brief but unsatisfactory definition of inflammation. The usual definition is a much longer one, and is either a resumé of the process or a description of the clinical symptoms. According to Ashurst, you must consider clinically the causes, symptoms, course, termination, treatment, and pathologically, the phenomena of function, nutrition, formation and destruction.

We have first in inflammation an increased action, though this may last but for a very short time. We may have for example, an increased function in the part, which is able to accomplish more than it did before. Now, this increased functional activity may only last for a short time, say half an-hour, or even shorter. Then we shall have a lowering of function, and in case the process is continued we may have a total abolition of function. This is also true in regard to nutrition. Then as to the destruction: here we have two terminations, one sloughing or gangrene, the other ulceration. In the first form, sloughing or gangrene, we have the macroscopical appearances; in the second, ulceration—a molecular removal of the microscopical.

The sources of inflammation are twofold: first, diseased or dead cells; and second, micro-organisms. In the first case a cell, from some cause or other, dies within the body and as a result it becomes an irritant and we may have all the signs of inflammation set up. The second condition is that which is due to micro-organisms, and is the one which is now being chiefly studied. In fact, it is difficult to conceive of an inflammation which has never been affected by micro-organisms. Therefore, the usual cause is considered a combination of the dead cells and the micro-organisms.

This constitutes the clinical form, which is described in works on surgery, and which is the variety that you will be called upon to treat.

As to clinical features of inflammation, pain, swelling, heat and redness—the pain is due to the fact that the exudate presses upon the terminal ends of the peripheral sensory nerves; the redness is due to the increased blood supply to a part, with a diapedesis of the red blood corpuscles; the swelling occurs because there is more fluid in the part, containing leucocytes, micro-organisms and their products, connective tissue cells, etc. The cause of the heat is a debated question; it is uncertain whether it is due to the fact that the arterial blood is there in larger quantity, or whether there is an increased chemical and mechanical change taking place in the part, or whether we have increased heat dissipation. There have been thousands of experiments made to ascertain the cause of this, but these experiments seem frequently to contradict each other. Where there are so many theories one may be quite sure that a combination best explains the fact.

We have in inflammation a substance known as pus. This has been described in the older surgeries by various names which it is necessary for you to understand. The old idea of a laudable pus is that pus which is of a greenish hue, with not a bad odor, and which occurs in those cases which are apt to recover. Therefore, it is a healthy pus. Sanious pus is that form in which blood and pus are mixed in varying proportions, from the slightest tinge to that in which it is mostly blood. Then we have the ichorous pus—which is

*Demonstrator of Gross Morbid Anatomy at the University of Pennsylvania.

thin and acrid. We have also the muco-pus and the sero-pus in which we have mucous or serum mixed with the pus.

Now, what is pus? Chemically, pus may be described as an albuminous fluid of a specific gravity varying from 1021 to 1042, containing the peculiar constituents of the tissue, whether they be cells, salts or organic substances with a mixture of leucocytes, micro-organisms and certain chemical bi-products, such as peptones, proteid compounds and leucin. If you open an acute abscess and examine under the microscope the pus, magnified about 450 times, you will find a great number of leucocytes, and these leucocytes will be practically of one size. There will be a very few cells larger than the leucocytes, which are connective tissue cells. If you will examine closely you will find that these leucocytes possess amoeboid movement. You will sometimes be able, especially on a warm day, to examine them very easily. If acetic acid be added to the pus, we shall have a clearing up of the protoplasm and the appearance of a number of nuclei, showing that at some time or other in the life history of the cell there had been an attempt at multiplication. When the pus is first being produced we have a number of micro-organisms present; but after a time the micro-organisms become rarer and you should not be disappointed in opening a large abscess if you are not able to find any micro-organisms at all. You expect to find it loaded with various micro-organisms. But the micro-organisms have died, have undergone some form of necrosis and have been carried off. This is well illustrated in tuberculosis. You might not find the tubercle bacilli in the cheesy glands of the neck, even though you should stain for them most carefully. How will you therefore demonstrate their presence? By taking some of the cheesy material and injecting it into a guinea pig —an animal which is especially susceptible to inoculation by tubercular material—and allow the bacillus to develope tuberculosis in the animal.

What micro-organisms are most frequent in the formation of pus? Many have been described. The list is a very long one and is steadily increasing. The way to remember them is simply to note that the names of such micro-organisms usually have the prefix pyo, which means pus; frequently pyogenes-pus-producing. They are also described in accordance with their color, citreus, albus, aureus, etc.; and by their shape streptococcus, cocci in chains; staphylococcus, cocci in bunches like grapes, etc. But not all micro-organisms that are thus capable of producing pus have the prefix pyo. The bacilli of glanders and tuberculosis are cases in point.

The cholera bacillus does not produce pus. This is important, as the anti-vaccine of Haffkine is capable of being introduced into man without fear of producing an abscess; only an indurated nodule is sometimes left at the seat of inoculation.

What are leucocytes for? This is a question that has been specially studied of late. When a micro-organism gains access to a part, has it the property of attacking the leucocytes, or have the leucocytes the power of attacking the micro-organisms? Do we know that the micro-organism has the property of eating up the leucocyte which has become granular or has undergone fatty degeneration? It is no uncommon thing to see five, six or seven micro-organisms inside of a pus cell. Now, did the pus cell swallow up the micro-organism, or did the micro-organism go into the pus cell in order that it might have food? That is the question. However that may be, the fact is, that when the leucocyte attacks the micro-organism (or the micro-organism attacks the leucocyte) we have certain poisonous products, which are in themselves capable of destroying the micro-organism which produced them. This is an important point. You know that in fermentation if the alcohol reaches twenty-five per cent. the fermentation ceases. So it is here. If the micro-organism has had an opportunity to grow, it produces a poison which is destructive to producer. Pathologists are now endeavoring to isolate such chemical substances from the micro-organisms with intent to confer immunity to disease by inoculation.

For a scald or burn there is nothing superior to wet bicarbonate of soda applied to the part.

According to Dr. Miles there is an abortive form of typhoid fever. These attacks usually last from nine to twelve days.

COMMUNICATIONS.

THE CURETTE IN OBSTETRIC AND GYNECOLOGICAL PRACTICE.

JNO. G. CECIL, M. D., Louisville, Ky.

The curette, like many other surgical instruments, has experienced seasons of favor and disfavor. At no time, however, as at the present, has its usefulness been so fully recognized. So much have the dangers attending the use of the instrument been magnified, that unquestionably there yet lingers in the minds of many, strong prejudices against it.

Many, in fact most of the objections that justly obtained before the application of aseptic precautions, are now no longer tenable. It can never be maintained that the use of the curette is entirely devoid of danger, but hedged about with all the modern methods of preventing septic infection, it may be stoutly claimed that the danger is reduced to a minimum in any case of whatever kind, where its use is called for. So, in any case, where the indications are plain, the most cautious and timid need scarcely hesitate in its application. It is hardly necessary to add that the use of this instrument, in the hands of a bungler, or careless manipulator, is capable of doing incalculable harm, despite aseptic precautions let them be ever so thoroughly instituted.

The good results that may be had are so manifold and great, and so far outweigh the dangers, that to enter a plea for a place for it in the armamentarium of the obstetrician or gynecologist, would be a work of supererogation.

When I say curette I do not confine my meaning to those bent wire affairs which have all along been regarded as harmless, and we might safely add, almost useless, at least in gynecological practice, but to the modern improved instruments with cutting edges.

The indications for the use of a dull or a sharp curette, depend upon the exigencies of each case, and must be left largely to the judgment of the operator. There is no doubt that much of the disfavor the curette has fallen into is due to the use of a dull instrument, where a sharp one was demanded.

Before referring to the special indications for the use of the curette, and this part of my subject alone would lengthen this paper beyond its intended limits, a brief consideration of the preparations and methods necessary to its proper and safe use, will not be inappropriate.

To begin with, curettage should be dignified by the name of an operation and the antecedent preparations should be just as jealously carried out as those, for instance, for an abdominal section. Many untoward results have followed because the operator deemed it only necessary to place the patient in position, introduce an instrument, itself probably not clean, and scrape away some foreign body, or adventitious growth.

Concerning the technique of curettage, I cannot do better than follow the suggestions of that most zealous advocate of the procedure, S. Pozzi, in his recent superb work on gynecology. The patient should have a full bath the evening or the morning of the operation. The rectum emptied by enema, the bladder by catheter, the external genitals thoroughly washed with soap and water, and afterward with a strong antiseptic solution; vaginal injections of sublimate solution 1 to 2000 should be enjoined twice daily for several days prior to the operation. On the day of the operation three injections are to be given, the first two at intervals of an hour, the third at the very moment of the operation. It must be borne in mind that if bichloride of mercury is used for douchings, that gynecological patients will safely stand stronger solutions than obstetric cases. Should the cavity of the uterus need powerful disinfection, (as in certain cases of gangrenous fibromatæ, intrauterine cancer with putrid fungosities, etc.) it is advisable to extend the douchings into the cavity. There may exist a demand for continuous irrigation, if so it is readily applied by means of the irrigating curettes or other devices. Though pain in many cases is not great, yet for the sake of thoroughness and control of the patient, an anæsthetic is demanded.

The operation may be satisfactorily done in either the dorsal or lateral decubitus. The vaginal walls are separated and held apart by retractors or a suitable speculm

in the hands of assistants. The first step of the operation is to fix the uterus with tenacula or Museux forceps. The cervical canal must be sufficiently dilated to permit the easy passage of the curette. This is safely and quickly accomplished by the graduated or the steel dilators. The choice of the curette is, as has already been hinted at, not a matter of indifference. In general terms it may be said that dull instruments are most suitable and safest for obstetric cases, while the sharp or cutting instruments are most serviceable in gynecological cases. The scraping of the cavity of the womb should be done in a systematic manner. Beginning at a certain point, say the posterior wall, every part of the surface should be carefully gone over until the starting point has been reached. During the progress of the scraping, if it is necessary from time to time to remove the detritus, this can be done by the spoon-shaped instruments, or by the irrigating tube. If it is desired the field of operation can be entirely submerged throughout the operation by an antiseptic solution, by simply elevating the hips of the patient and filling the vagina with the fluid. When satisfied that every part of the cavity has been curetted, it should be thoroughly irrigated with a hot antiseptic solution, this followed by application of some mild caustic or packed with a strip of iodoform gauze. The patient should be kept in bed for three or four days at least, even in the simplest cases. Though to emphasize the safety of this operation under antiseptic management, I have seen surprisingly good results follow the use of the curette in gynecological cases, with no bad effects whatever, that were operated upon in the University outdoor clinic, that were allowed to go some distance to their homes, and where it is certain injunctions to remain in bed were not followed. It has been extremely gratifying both to Prof. Anderson, with whom I have been associated, and myself, that not one unfortunate complication has followed this method of treatment, in the many cases that have been subjected to it, even with the rather incomplete antiseptic possibilities of an outdoor clinic. But, even with so good a record to substantiate the foregoing, similar risks are not advised, only mentioned to demonstrate the possibilities of this treatment.

The special indications are so numerous that even brief mention of them in this connection, will not be permissible. In obstetric practice, there are two conditions that demand a curette, and demonstrate its usefulness most plainly; they are persistent hemorrhage, due to retained secundines or fungous degenerations of the endometrium after labor or abortion; and the septic conditions of the puerperal patient. It is in this class of cases that the dulled curette finds its greatest field of usefulness, and yields the most brilliant and satisfactory results. Particularly in those annoying hemorrhages that follow incomplete abortions, does the curette answer the demand. Instead of temporizing with ergot, hot douches, or other hemostatics, the curette is the certain, safe, and rapid substitute. Much time and annoyance is saved, and the subsequent progress of the case is most gratifying. In the management of septic conditions that follow labor, either premature or at full term, I am disposed to claim for the curette an important place. Any one who has made even a macroscopical post-mortem observation of the endometrium of a case of puerperal septicemia can see at a glance the indication for the curette. Here is a cavity, the lining membrane of which is a decomposing mass. The most important part of the management of such a case is to cleanse this cavity and afterward keep it clean. I do not advocate inconsiderate invasion of the puerperal womb, on the contrary, unless the indications are plain, am much opposed to it. I am satisfied that many cases, especially in private practice, are lost, because we are either too slow, or else lack courage to apply remedial measures that give us the best, and often, the only hope. I refer especially to the intrauterine douches and the curette, and it should have a fair trial, even to the extent of continuous irrigation. If the continuous irrigation fails, recourse to the curette is the *dernier resort*. The curetting will not reach poison that has already been taken up by the lymphatics or bloodvessels, but it will limit the further production of it. With the curette the sloughing surface is bodily removed, and with it the focus of infection; in fact, we are treating this as we do any sloughing surface in surgical cases. It will be seen at a glance that this procedure should not be deferred too long, if we would reap the

benefit. Many cases, apparently hopeless, may be saved by this active and radical measure.

The limits proposed for this paper will forbid extended account of the application of the curette to many of the particular cases of gynecological character, or to detailed description other than what has previously been mentioned, of the method of using it.

In those obstinate cases of so-called "uterine or cervical catarrh" that become such an annoyance to the busy practitioner—and such a godsend to the poor but aspiring young gynecologist—because they are not inclined to get well, of all the curative procedures that are lauded by their respective authors, none promise so well as a vigorous attack with a sharp curette. My own experience with the curette in this class of cases has been uniformly satisfactory. The cutting must be deep enough to remove the diseased follicles to their entire depth, and when this is done, certain relief will seldom fail.

Painful and intractible cases of membraneous dysmenorrhœa can be most effectively treated and cured by judicious use of the sharp curette. The operation should be performed just prior to menstruation.

The small sized sub-mucous fibroid tumors that cause excessive and dangerous hemorrhage, can be brought under the benign influence of the curette with signal advantage. The hemorrhage in these cases is not so much from the tumor as from the uterine mucosa, which is kept in a constant state of congestion and irritation by the presence of the fibroid.

Much can be said of the value of the curette in the management of cases of uterine cancer that are beyond the reach of the more radical operations. The unfortunate patient can be made more comfortable to herself, her friends, and attendants; the rapid progress of the destructive process may be in a measure stayed; septic infection can, for a time, at least, be warded off, and alarming hemorrhages can sometimes be anticipated and put under more perfect control. The scrapings of the curette can be utilized for diagnostic purposes when cancers are suspected in the body or fundus of the womb.

Enough has been said to fully demonstrate the usefulness of this instrument in the gynecological field. While much may be said of the indications for the curette, much has also been said as to the contra-indications, perhaps too much. Many modern authorities seem disposed to ignore such contra-indications as have become classic, namely, acute inflammation in and about the uterus and its appendages, and, also, chronic inflammations in the same regions that have left the womb fixed by many adhesions, and which seem disposed to rekindle upon slight provocation.

I cannot yet bring myself to the point of advocating the bold use of this instrument in the presence of such conditions, when the results may be so dire and regrettable.

The Remedial Use of Apples.

Chemically the apple is composed of vegetable fibra, albumen, sugar, gum chlorophyl, malic acid, gallic acid, lime and much water. Furthermore the German analysts say that the apple contains a larger percentage of phosphorus than any other fruit or vegetable. The phosphorus is admirably adapted for renewing the essential nervous matter, lecithin of the brain, and spinal cord. It is, perhaps, for the same reason, rudely understood that old Scandinavian traditions represent the apple as the food of the gods, who when they felt themselves to be growing feeble and infirm, resorted to this fruit renewing their powers of mind and body. Also, the acids of the apple are of signal use for men of sedentary habits, whose livers are sluggish in action, those acids serving to eliminate from the body noxious matters, which, if retained would make the brain heavy and dull, or bring about jaundice or skin eruptions and other allied troubles.

Some such an experience must have led to our custom of taking apple sauce with roast pork, rich goose, and like dishes. The malic acid of ripe apples, either raw or cooked, will neutralize any excess of chalky matter engendered by eating too much meat. It is also the fact that such rich fruits as the apple, the pear and the plum, when taken ripe and without sugar, diminish acidity in the stomach, rather than provoke it. Their vegetable sauces and juices are converted into alkaline carbonates, which tend to counteract acidity. —*N. Amer. Prac.*

SOCIETY REPORTS.

THE SURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting of October 10, 1892.

Dr. Jno. G. Cecil, Vice President, in the chair.

FRACTURE OF THE PATELLA.

Dr. W. C. Dugan: I simply present this patient to show the result of an operation for fracture of the patella. It is a little early yet to tell definitely what the result is going to be, but there seems to be a good bony union, and I believe he will have perfect motion in the joint. Eighteen weeks ago a wagon ran into this man and mashed his patella. I saw him a short time afterward and the fragments were separated at least three and one-half inches; it was a transverse fracture, with two or three fragments broken entirely out. The operation was done one week afterward, the fragment united by silkworm gut. You will observe two or three fistulas still open.

One word concerning the anatomy of the muscles of the patella. It is usually stated in our books that the quadratus extensor, or the triceps extensor, is inserted into the patella. This is clearly a mistake. By careful dissection the muscles can be removed leaving the patella attached to the ligaments and serous capsule of the joint showing that the muscles are not in reality attached. In the case above reported there was great distension of the joint at time of operation, and he had much pain from this distension. He has suffered little or no pain since being operated upon. I went to see this case without my bone drill, and holes were made in the bone with a pair of barber's scissors. He has not had an untoward symptom, and I believe will make an uneventful recovery. I am decidedly in favor of the open method of treating these cases, when there is much separation. If the fragments are in good position, that is when the muscular aponeurosis is not torn, I do not consider it advisable.

DISCUSSION.

Dr. A. M. Vance: I have never performed the operation of suturing the patella, but have assisted in several operations of the kind. I doubt very much if a bony union can be obtained in fracture of the patella without the operation advocated by Dr. Dugan; still, I must say that very firm and unyielding union can be obtained by proper mechanical means, if treatment is continued a sufficient length of time. I have several cases where a functionally perfect limb resulted; in fact, have never failed to get a very useful limb after this injury.

REMOVAL OF APPENDIX, DEATH FROM URÆMIA.

Dr. Jas. Chenoweth: I have a specimen that I would like to show: It is an appendix vermiformis removed two weeks ago last Friday, from a man thirty-one years of age, a farmer, who had always been in good health, and a strong, athletic looking subject. I saw him about a year and a-half ago with a slight attack of catarrhal appendicitis, little or no fever and not much pain. He stated to me then that he had two similar attacks two or three years before; he recovered from this attack and I heard nothing more of him until two weeks ago last Friday. That morning he came to town from the country, feeling a little sick; did not eat any breakfast; suffering some pain in the right side. I saw him two hours afterward; he had gotten very much worse; suffering intense pain; cold, clammy perspiration; suffering a great deal from shock; pulse 60 when normal, was then 82; temperature 99.5° F.; abdomen slightly tympanitic even at that time. I thought he probably had perforation of the appendix, or it was on the verge of perforation, and had him sent to the Infirmary, advising immediate operation. Two hours after reaching the Infirmary pulse was 106, temperature 101° F., and still suffering intense pain; abdomen more distended; very tender, could hardly touch him at all on the right side. I operated upon him at two o'clock, seven hours after the attack came on. I found the intestines greatly distended and very much reddened, showing evidences of peritonitis. The colon protruded as soon as the abdomen was opened; by following the colon down, without much difficulty I found the appendix low down in the pelvis, slightly at-

tached to the wall, not very firm and easily detached; it was brought up and found to be about the size of a finger, and three or four inches long. It had to be handled carefully to prevent rupture; it had not perforated but was very much distended, and evidently on the verge of perforation. The appendix when removed contained two small fecal concretions. The patient was on the table about twelve minutes; pulse at the time about 60. He was very much nauseated, and vomited severely after the operation; no action of the bowels, and still considerable distension. By repeated enemata his bowels were started, the nausea subsided, and he seemed to be doing very well. The first night after operation temperature was 102° F. but as soon as his bowels commenced to act, temperature went down to normal, running from 98.5° to 99° F. The stitches were removed on the eighth day and union had taken place. On the ninth day there was a little discharge from the lower stitch, where some fluid collected between the peritoneum and muscles; temperature on the tenth day went up to 101° F.; I made an examination and found a little discharge collected through the night; there was no inflammation of the skin and no tenderness in the right side; never had any pain after the operation. I opened the lower part of the wound and found a little cavity filled with fluid; the peritoneum had united perfectly, leaving no tenderness and no induration. On the morning of the fourteenth day temperature (which had gone down after cleaning out this little accumulation to 99° F.,) went up to 101° F.; he seemed rather restless and nervous, but talked in a perfectly rational manner and felt quite well. About two hours afterward I had a telephone message to come to the Infirmary as the man was unconscious. I went out immediately, found the patient in a comatose condition, gave him a hypodermatic injection of whiskey; pulse about 150. He never fully gained consciousness and died about 8.30 that night. He had been passing water in the natural way, and there was no occasion for using the catheter, but on my last visit to the Infirmary I introduced the catheter, and drew off some urine, found it loaded with albumen, death being due evidently to uræmia.

DISCUSSION.

Dr. E. R. Palmer: Did you make a post-mortem, and were the kidneys ever examined?

Dr. Jas. Chenoweth: No post-mortem was made, and the kidneys were not examined.

Dr. W. C. Dugan: Do you think the nephritis was caused by the anæsthetic? I have seen several cases of suppression following operation, but they came on within the first twenty-four hours, and every one after chloroform anæsthesia.

Dr. Jas. Chenoweth: I believe the man had nephritis before the operation. He became very much cyanosed when taking chloroform. While he had never been sick much, I believe that the nausea was caused by some trouble with the kidneys. I never saw a wound do better, and the abdomen was perfectly flat on the first day after the operation.

Dr. E. R. Palmer: My idea of the case is that death was caused by kidney lesions, such conditions any man who examines much for life insurance will often recognize. It is very common to find bad kidneys in young men, and I believe in this case a defective kidney was the cause of death. Of course the exciting cause was the operation, and the consequent shock.

Dr. A. M. Vance: I saw this patient in the emergency, and recognized the probable nature of the coma and was very much interested in the case. It occurs to me that probably this man may have had septic nephritis—that there may have been a septic inflammatory condition of the kidney. I think it would have been very interesting to have held a post-mortem on this case to determine whether it was ordinary nephritis, or septic nephritis. This small accumulation of pus might have been sufficient, though he did not show marked evidence of sepsis generally. It is certainly a very interesting case, and one that proves to us the rightful procedure, of always making a very thorough examination of the renal secretions whenever possible.

Dr. E. R. Palmer: Of course I am particularly interested in cases of renal lesions as a factor in fatal results, and those of us who are working strictly in that direction know how important it is to have a very careful analysis made of the urine, not simply a chemical albumen test, but a very careful examination of the sedi-

ment to try and determine if there be any renal trouble, and the nature and extent of it. But the point I want to make, and I have thought of it often, is that in this age of rapid advances of a more purely scientific nature in surgical work, that we do not insist enough upon post-mortem examinations. I do not see why every city should not have one or two men who are known as "Post-Mortem Experts." I have seen a number of post-mortems where there was extensive degeneration of the liver, for instance, in which there was not a suspicion of liver complication during life, and consequently no treatment instituted for that organ. I believe in the case reported by Dr. Chenoweth, if a post-mortem had been held it would have been found that the man had serious renal trouble which probably existed prior to the operation for appendicitis.

Dr. W. C. Dugan: I had the pleasure of seeing this case on the fifth day after operation with Dr. Chenoweth, and the patient was then suffering from nausea, otherwise he seemed to be doing very well; pulse about 78, and did not indicate sepsis. I am sure the patient died of uræmic coma as stated by Dr. Chenoweth. The question of coma after operation is one of great interest, especially as I have lost two patients recently from this cause, but the coma in both instance came on immediately. Post-mortem revealed disease of the kidney in both cases and neither of the patients had any urine after the operation.

I am sorry that Dr. Chenoweth's patient died, as it will go down as a fatal case of appendicitis, when the operation for this trouble was a complete success, the patient eventually dying from another cause.

Dr. J. M. Mathews: I think the Doctor should be commended for the diagnosis he made. I have no doubt that in the country districts, and perhaps sometimes in the city, patients have been allowed to die with appendicitis—so-called biliary colic, passage of gall-stone, etc.—without operation, when they might have been saved by surgical interference. In regard to the contents of the appendix in these cases, there is a popular impression existing, not only among the laity, but the profession, that it contains grape seed and other foreign bodies. Now, it always occurred to me that in the majority of cases the contents will be found to be fecal concretions. I notice Dr. Chenoweth in his report stated he found a fecal concretion.

Dr. W. C. Dugan: In this connection, I remember looking up the subject sometime ago, and out of 252 cases of appendicitis reported by several pathologists, there were irritating bodies found in the appendix in 112; and out of this number there were ninety-nine which contained fecal concretions or enteroliths, and in thirteen there were found various kinds of fruit seed or some other foreign body. In the majority of cases I am quite sure there is no foreign body. The hobby of grape seed, blackberry seeds, etc., is entirely a mistaken idea, in my judgment.

Dr. Jas. Chenoweth: As to the cause of the trouble in this case, I think if you will examine the specimen you will find the opening into the bowel was very small, and probably the attacks he had before were simply produced by the appendix becoming distended by fecal matter. The concretions were not very hard. I think the irritation was caused by the distension, and then threatened gangrene from the pressure. As for the uræmic coma, I believe as I look back on the case that the man undoubtedly had disease of the kidneys prior to the attack of appendicitis for which the operation was performed, and believe that the kidneys were responsible for the way he acted under chloroform; he was very much cyanosed and nauseated, more than could be accounted for in any other way, at the time, and after the operation. He had no septic symptoms at all as far as the wound was concerned; there was simply a small collection of fluid at the bottom of the wound between the peritoneum and muscles.

Dr. Jno. G. Cecil presented a paper, "The Curette in Obstetric and Gynecological Practice." (See page 50).

DISCUSSION.

Dr. E. R. Palmer: I think Dr. Cecil's paper is one of the best that has ever been read before this society. I have a number of cases of gonorrhœal endo-cervicitis and metritis constantly under treatment, and in the management of these cases I have been doing a good deal of rough curetting, but with a dull instrument. I have had no trouble in passing the curette to the fundus and following the doctor's suggestion of beginning at a certain point

and returning to that point, curetting the entire interior of the uterus, removing a considerable quantity of muco-purulent material; there has usually been considerable bleeding following the operation. The last patient I operated upon was to have returned to-day; whether there has been a continuous hemorrhage or not, I am not informed. I am certain, however, if there had been any further trouble I would have heard of it. I am very favorably impressed with the idea of free curetting. I have frequently irrigated the uterine cavity with 1 to 500 bichloride of mercury solution. If there exists an obstructed or diseased tube, then I carry my syringe up into the uterus directing the point toward that tube, and throw a stream of 1 to 500 bichloride solution, hoping it will go into the tube rather than with the fear that it may go into it. There is no question but that a great deal of this solution is left in the uterine cavity afterwards. I rather hope that some may be left there. I must say that in my experience, extending over more than twenty-five years, I have never seen any bad results further than an occasional sharp pain for a half hour or so, follow a free washing of the interior of the uterus. Of course my attention to the uterus now is confined almost entirely to that organ when it is probably the seat of venereal lesions. I shall certainly provide myself with a sharp curette and use it hereafter in these cases in preference to the dull instrument I have heretofore used.

Dr. F. C. Simpson: Just in this connection, I want to say that in the last week I have had occasion to curette the uterus of a woman who had aborted, followed by continuous flooding. I went over the whole cavity with a dull curette, removing quite a quantity of fungus material. She returned to-day and reported that the hemorrhage had entirely ceased. I examined her with a speculum and found a healthy condition. There was some little granulation around the opening in the cervix, but she had been relieved of that uncomfortable, heavy feeling, and bearing-down sensation. I simply mention this case to corroborate what has been said concerning the use of the curette.

Dr. J. G. Cecil: I have very little to say in closing. In dilatation of the cervical canal I have never used tents at all. I can frequently accomplish dilatation in a very little time to such extent as to admit of the free and easy use of the curette without anæsthesia, using a Goodell dilator. I simply dilate the cervical canal sufficiently to enable me to freely use the instrument, no further. I am very sorry that the limits of my paper would not admit of a detailed report of a number of cases both in obstetric and gynecological practice. I am more particularly interested in the use of the curette in gynecological than in obstetrical cases, and while this is a Surgical Society, still the question of its use in obstetrical cases demands some attention. I should have been very glad to have heard a discussion upon the use of the curette in obstetrical cases. While the cases I have referred to as being followed by uniformly good results in the University outdoor clinic, many of which have been put in a carriage and driven two, three and four miles, those results were obtained in gynecological cases, but I have had equally as satisfactory results in obstetric cases; and this was the point I wished particularly to hear discussed. I think the fear in regard to the use of the curette has been much magnified in the minds of many obstetricians.

Concerning infection of the puerperal womb: I have in mind now the case of a young woman who miscarried at three or four months, and had evidences of septic infection, so much so that her attending physician became very uneasy. I put this patient upon the bed and without anæsthesia irrigated the womb thoroughly, and with a dull curette scraped away everything from the cavity, and had the satisfaction of seeing the woman make a perfect recovery without any further infection. I have recently been very favorably impressed by an article, by Pryor, of New York, on this subject. He takes the position (and I perfectly agree with him) that we ought not to allow patients to die of septic infection of the womb without giving them the opportunity of the advantage and benefit to be derived from the curette, at least the possible chance of preventing the spread of infection and limiting that which has already been observed. I think before many years have elapsed the curette will be used in common practice.

PATHOLOGICAL SPECIMENS.

Dr. W. L. Rodman: The patient from whom this specimen (Testicle) was re-

moved gave the following history: He was an exceedingly robust, vigorous young man, about twenty-four years of age, sent to me by a medical friend; I saw him for the first time about ten days ago. He had a hernia on the right side, which he tells me was cured by a truss, and had been cured for five or six years. He had a retained testicle on the left side. The testicle, which was small in size and soft in feel, was found located just in the external abdominal ring. It was not possible to pull the testicles down into the scrotum, on account of the shortness of the cord. Owing to its very soft consistency, and the probable functional inactivity, I advised immediate removal. The patient consented conditionally, saying that, of course, he would like to have it removed, provided there was no chance of saving it. I told him that when we cut down upon the testicle if we found it in a healthy condition, an effort would be made to preserve it by transferring it to the scrotum, I operated upon it and after cutting down around the organ, found it very small and even softer than I suspected, and that it had undergone cystic degeneration. The testicle was immediately removed, transfixing the cord and tying each way. I am inclined to the opinion that all retained testicles, even in the inguinal canal, or outside of the external ring, should be removed. When retained in this situation they are usually small and imperfectly developed organs, without function and there is a decided tendency to undergo sarcomatous change.

DISCUSSION.

Dr. A. M. Vance: I have seen a great many cases of this character, and believe in the majority of them the testicles are practically useless.

Dr. E. R. Palmer: I believe that all testicles retained anywhere in the canal, are not only useless, but are dangerous; in the abdominal cavity they may be active and useful. I have already reported one case of a bridge builder who came to me for treatment for another trouble, having incarcerated testicles in the groins. He called my attention to this condition and asked me if I thought he could get married. I told him that I believed he was sterile, but to bring me a sample of his semen and I would make an examination of it. This was done and I found the semen utterly devoid of spermatozoa. He did marry but his wife never conceived. I have never seen a case of malignant degeneration of the testicles from being retained and have seen a great many monorchids and cryptorchids.

Dr. A. M. Vance: I have treated a great many cases for replacement of the testicles, and have often succeeded. I have a case under treatment now where a surgeon in town had applied a truss over the testicle with the idea of pressing it back into the belly. A number of times have I taken trusses off from retained testicles being treated for hernia. In the case above referred to in which there had been an effort made to force the testicle back into the abdominal cavity, I have succeeded in getting it down in a month or six weeks into the top of the scrotum by the application of a truss over it and careful manipulation. I believe in the majority of infantile cases, where the testicle is out of the canal at all, or even approaching the external ring, it can be replaced into the scrotum by a little patience on the part of the mother.

Dr. W. C. Dugan: I believe that Dr. Rodman did exactly right in removing the testicle, as, when retained in the canal they are very prone to undergo malignant degeneration. The question I want to bring up is this, and, as I have stated before,—when these cases come under our observation early in children, if everything else has been tried, and the testicle remains in the canal, and we cannot get it down, and the mother and father are very anxious to save the testicle,—inasmuch as we know that when these testicles are in the cavity of the pelvis, they are normal and serviceable, and a testicle in the canal is subjected to pressure and liable to undergo malignant or inflammatory degeneration, that these testicles should be put back into the pelvis. I think this will be the operation in the future.

AN INSURANCE QUESTION.

Dr. W. L. Rodman: I have seen in the last few days the most remarkable case that I have ever seen in my life—the most deplorable ending to it. Last Thursday I saw a gentleman for an accident company, about fifty-five years of age, laborer in one of the breweries of this city, who, by some accident, had sustained a simple fracture

of the distal phalanx of the great toe near the joint. I saw him for the first time Thursday afternoon, after considerable swelling had taken place. I ordered hot applications, saw him again Friday and he seemed to be getting along all right. I saw him again on Saturday afternoon, five o'clock, and noticed he was a little nervous. His wife said that he had some fever in the forenoon, but did not seem to have any when I saw him at five o'clock in the evening. I did not use the thermometer, however; he said he was feeling very comfortable, and remarked that the hot water had relieved the pain. I told him he was doing so well that I would not call again until Monday. I learned to-day (Monday) that he was dead. I at once went to the brewery to learn the particulars and found that on Sunday morning about two o'clock he had jumped out of the second story window; did not hurt himself much in jumping; wandered around town, went to the brewery and remained there two or three hours; bought two bottles of whiskey (pint bottles) and wandered out to the country and was seen six or seven miles from town yesterday at noon. He was very thirsty and went to a farmer's house, and asked for a drink of water, then tried to climb up the side of the stable, saying that he wanted to get into his room. He wandered about all yesterday and was found dead about four o'clock this morning with two empty pint bottles in his pocket, having evidently contained whiskey. This man had been working at the brewery and had probably been in the habit of drinking a great deal of beer; when I saw him on Saturday afternoon I did not tell him to drink more or to drink less. I thought as he was a little nervous possibly he was not getting quite as much beer as he was accustomed to. The question is, what ought the accident company to do in a case of this kind. I am very frank to say that the man may have had delirium, even as a result of a slight injury like that. It is questionable as to how much was due to whiskey, and how much was due to fever, the result of this simple fracture of the distal phalanx of the great toe.

I remember reporting to this Society four or five years ago a case of delirium after fracture of the leg. I held at the time that the delirium was due to the fracture.

DISCUSSION.

Dr. E. R. Palmer: My experience with these men who work about breweries and about beer saloons, and who are constant beer drinkers, is that they usually wind up the day with whiskey or brandy; that beginning the next morning they drink whiskey or brandy, which, in both or either instance, is usually a very inferior article, and begin their beer again about ten o'clock in the day. I think the case reported is clearly one of surgical delirium in the drinking man.

Dr. W. C. Dugan: The question is whether the accident company should pay the amount of insurance.—I think they should. Why? Because, undoubtedly, the fact was known that the man in question was a drinking man at the time the insurance was taken out. The company assumed the risk, and, I think, should pay for it. It may be true that the man developed delirium tremens, and he was practically predisposed to it. On the other hand, his death might have been the result of uræmic coma.

Dr. H. H. Grant: I have seen a great deal of delirium tremens, and it has been my observation that it nearly always occurs, for some reason, after fracture or other minor injury. In the case reported by Dr. Rodman, I do not think the man would have sustained the injury if he had been carefully watched and properly nursed. I believe it is fair to decide that the accident was not the cause of this man's death, but it was the predisposing cause. I do not think the accident company is responsible for the reason that the man was under the care of his family and should not have been allowed to jump out of the window, subjecting himself to that risk. I think the position taken by Dr. Dugan is hardly the proper one for us to hold.

Dr. W. L. Rodman: I failed to state that this man lived up stairs with his wife, who is an invalid, and, therefore, not able to restrain him. I shall certainly advise the company to pay the insurance. Had he not received the injury, he would not have had delirium tremens.

Many cases of death are caused from vasomotor paralysis of the heart, superinduced by the administration of alcohol in the practice of physicians.—Quirmby.

THE CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting of December 13th, 1892.

DOUBLE EXCISION OF THE KNEE.

DR. A. M. VANCE: I simply present this patient to show the result of double incision of the knee for infantile paralysis. The boy is about nine years old, very small for his age; his body is fairly well-developed but the legs are very small. I first operated upon the left leg, then after a lapse of about five months excised the right knee. You will notice I have put one leg in slight flexion, the other in hyper-extension, by this means hoping that he may be better able to balance himself in walking. I used no suture whatever in uniting the bones, the plaster dressing serving to keep them in apposition; I first removed the patella, then about a half inch of the tibia and femur. There has not been the slightest sign of inflammatory reaction or suppuration from either operation, proving the power of asepsis in these cases. I have done this operation five times on the knee, and twice on the ankle; the last patient operated upon died about ten days after the operation with some trouble of the heart.

DISCUSSION.

DR. I. N. BLOOM: In case the operation had not been performed and the paralytic condition allowed to exist there would have been complete atrophy of the muscles. I would like to ask Dr. Vance if he expects muscular development now.

DR. A. M. VANCE: All the calf muscles that move the foot and are not paralyzed, will develop by use.

Dr. W. O. ROBERTS: There seems to be a good, bony union. Have you ever noticed in any of these cases, after you have apparently secured good, bony union, it afterwards limbers up?

Dr. A. M. VANCE: No, I have not; the bony union has always been permanent.

DR. W. O. ROBERTS: One important point in an operation of this character is to get, if possible, bony union, and in order to do that it seems to me you are bound to take off the cartilage of both bones. If you do not you get what is called a "flail" joint. Another point you have to be exceedingly careful about in removing a piece of bone is, not to take off too much; if you do the bone ceases to grow. This is a very important point in cases of resection in children.

CASES EXHIBITED.

DR. T. P. SATTERWHITE: Dr. Dugan, I believe, performed a laparotomy upon this patient about a year ago; the stitches inserted at the time seem apparently to have cut through, and there is a kaloid condition running across the abdomen from each stitch as large as a small lead-pencil. She is a Polish girl about eighteen years of age. The operation referred to, as I understand, was an exploratory one, owing to some ovarian trouble which was supposed to exist. However, everything was found to be in an apparently healthy condition, consequently nothing was removed.

The point that I wish to call particular attention to is, that she now claims to have an evacuation of the bowels only once in three or four weeks. She speaks English so imperfectly that it has been exceedingly difficult for me to obtain a full history of the case. She tells me that she suffers intensely, probably from the accumulation of fecal matter, and that a colotomy has been proposed for her relief. That is a point upon which I desire to obtain the judgment of the Society—as to the propriety of further operation. She came to me for advice as to whether she should submit to an operation. She says that one-half of her body, (left side) is perfectly devoid of sensation; a needle can be thrust into the body on that side without pain; there is perfect sensation of the opposite side. There is no loss of motion of any portion of the body, but simply loss of sensation on one side, which has existed for about eleven months. She has been troubled with constipation for about a year.

CASE II. Many of you have seen this patient as he has been in the city hospital a greater part of the time for the last year or so. I simply had him come here to show the development of the superficial veins on the upper part of the trunk. These veins commenced enlarging about a year ago and you will observe now they are nearly as large as your finger. A peculiar feature is that the blood flows downward

in these veins, as can easily be proven by compressing them at either extremity.

DISCUSSION.

Dr. W. H. Wathen: If I understand correctly, one of the especial reasons for reporting the first case, was to get the sense of the Society as to whether colotomy is indicated. This woman consulted me some six weeks ago upon two or three occasions, but I found that she was not a patient that would interest me especially, and declined to see her again. I can see no indication for a surgical operation of any kind upon her bowels, or upon her uterus or its adnexa. Colotomy could do no possible good, but might do a great deal of harm, because it would bring about a very disageeable condition by keeping the patient constantly soiled with fecal matter. I can not understand why colotomy should have been suggested, because there is no apparent obstruction in any part of the canal, and we have no positive assurance that this woman has constipation at all. In fact, I am inclined to the opinion that she is having evacuations with comparative regularity. I do not mean to claim that she is purposely deceiving the profession, for she may be absolutely honest in what she says; she is probably insane upon the subject. Were she having as few evacuations as she claims, there would be conditions that do not exist.

Dr. T. P. Satterwhite: In regard to what Dr. Wathen has said: "That there would be some constitutional disturbance if a patient did not have an evacuation oftener than stated by this patient," let me state: Several years ago I had an Irish servant girl with me about thirteen years, and she never had an action of the bowels for three and four weeks at a time and during this period she was in excellent health. Never was sick in the thirteen years, and she reported to me at the time that there was a woman next door in exactly the same condition.

Dr. I. N. Bloom: You are all doubtless familiar with the report in physiology of a man who went eight months and sixteen days without having an action of the bowels, and was in perfect health all the time, and when he did have an action there was a large amount of fecal matter, over fifty pounds, I think. Cases of this kind are not so very uncommon. An examination of the abdomen is bound to disclose an abnormal condition, while the sensations of the patient may be those perfectly consistent with good health.

Dr. A. M. Vance: I have seen a great many cases of varicose veins on the trunk, and do not think the condition very uncommon. I expect I have seen at least twenty-five cases, some of which are more marked than the one shown by Dr. Satterwhite.

GANGRENE FOLLOWING FRACTURE OF ARM.

Dr. W. O. Roberts: About two weeks ago I was called to a neighboring town to see a gentleman who had fallen a distance of some twenty feet, sustaining a complicated fracture of the bones of the forearm. The arm was put up in plaster dressing and kept there several days. At the end of the week his physician discovered evidence of gangrene. When I saw the patient, seven days after receipt of the injury, gangrene was quite marked and extended to within two inches of the elbow joint. The parts above were very much swollen, and there was considerable contusion and ecchymosis of the arm on the inside, as high as the axillary space. The patient's temperature was 104° F., pulse 130. The temperature the day before, the doctor told me, was only 101° F.; on the morning of the day I saw him it was 102° F. I saw him about four o'clock in the afternoon and advised immediate amputation, and did the operation at the junction of the middle third of the humerus. I had a letter from the doctor, a week after the operation was performed, saying that at nine o'clock at night of the day of the operation the patient's temperature had fallen to 100° F. and since that time it had not gone above 99°, and that there was union nearly throughout the whole line of the incision.

Excision of the tympanum and ossicles gives beneficial results only in about forty-six per cent. as to the tinnitus, but no noticeable improvement in the hearing.

Doctors, lawyers and divines in our American civilization are prone to use tobacco, not simply for its sedative effect, but for companionship, and so to use it to excess.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 = 18 = 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on tria for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JANUARY 14TH, 1893.

EDITORIAL.

A DEPARTMENT OF PUBLIC HEALTH.

Why not establish a National Department of Public Health, with its chief a member of the Cabinet? The present seems to offer a most favorable opportunity. The subject has been frequently discussed of late years, but apart from the establishment of a national quarantine supervision, no suggestion on this line has been made since the subsidence of the late cholera excitement.

None but a cavilling patriot or a ward statesman would deny the usefulness of the Department of Agriculture. It has rendered good service within its sphere. At any rate, it has succeeded in restoring the position of the American Pig abroad. It costs some million dollars to do this, but it secures large profits for pork packers and enables them to maintain without cost their representative in the foreign market.

While thus insuring his alien friends against infection from "pork measles," the American tax payer maintains his personal liberty to enjoy all the privileges and delights to be secured from Trichinosis. Indeed he could hardly do otherwise for it would require Federal watchfulness and authority to secure him immunity, and this could not be had without infringing on State Rights. Any national laws to regulate adulterated or impure food products must meet with the same objection.

If the Federal Government is able to spend money liberally to investigate the ills that animals are heir to, and to enforce measures to prevent and cure such ills; if it can indulge in costly efforts to make sterile lands fertile; if it can explode thousands of dollars in making stage-thunder, hoping to seduce cloudless skies into surrendering rain; if it can control and regulate interstate commerce—it would not seem an undue centralization of power to charge the National Government with the care of the health and happiness of the citizens of states which are inter-dependent in this matter perhaps more than any other.

Of course if public health were raised to a plane that required it to support the tremendous dignity of a government "Department" and

"Show the force of temporal power,
"The attribute to awe and majesty,
"Wherein doth sit the dread and fear of Kings"

it is altogether probable that its beneficial action would be clogged by that network of red tape which seems necessary to prove the existence of governmental undertakings. But with all its pretentious formality it would be infinitely better than the system now obtaining, where the health officer is the creature of local politicians and the office is used to repay political obligations without reference to its importance or to the qualifications of the incumbent.

The health officer in any large seaport may, from a position of comparitive insignificance, suddenly be charged with responsibilities that would strain to the utmost the resources and capabilities of the best trained and most experienced scientific specialists of the world. It is simply impossible for any ring-trained politician to rise equal to such an emergency. Only a thorough scientist supported by the power of the Federal government can successfully contend with the Devil of Moneyed Interests on the one hand and, on the other, the Deep Sea of the Welfare of sixty-five millions of people.

Two measures have been presented to Congress as steps toward securing national quarantine control; at best but wretched caricatures of what is needed. One proposes to attach quarantine to an existing branch of the service, which might be able to care for it if it had nothing else to do. The other proposes absolutely nothing.

The first measure, now pending in the Senate, is apparently objectionable to certain disinterested patriots. For it threatens injury to the steamship companies concerned, in that it does not consider their dividends superior to the welfare of United States citizens. Again it appears to be totally oblivious to the time honored rights of "effete monarchies" to unload their paupers and criminals on American Institutions. Finally it unwinds the swathing bandages of that mouldy mummy States Rights.

As the bill is constructed on the "nickle-in-the-slot" principle the insertion of sufficient *plaques* might bring out enough amendments to remove these and all other objections.

It may be noted that States Rights were not pressed with any degree of persistence when the Marine Hospital Service was detailed to stamp out yellow fever in Florida, and saved the nation from a "visitation of wrath" that the combined "righteousness" of local health authorities could not have averted for a moment.

Quarantine is not the only function of such a department. It is not the chiefest even. The immense subject of vital statistics in its myriad ramifications is of untold value to the nation, practically as well as scientifically.

If infectious or contagious disease among animals is of sufficient importance to require government authority for investigation, prevention and cure, it would not seem unreasonable nor yet undesirable for the government to undertake the watch-care of analogous conditions in man. If it could be accomplished in no other way, it might possibly be smuggled into the department of Agriculture under the plea that man is only an "articulate speaking" animal.

GYNECOLOGY AMONG THE INSANE.

The secular papers with an inspiration commendable for energy rather than discretion, announce that the State Board of Charities has prohibited, as "illegal, brutal, inhuman and not excusable on any reasonable ground," the practice of gynecological surgery upon insane women at the Norristown Hospital. The breeze is

caused by the alleged action of Dr. Bennett in allowing operative procedures to be undertaken on a series of cases in hopes of relieving or curing the mental conditions by removing the probable physical causes. The State Board is fortified by an opinion from its legal member, which opinion shows better acquaintance with law than with medicine. We venture to say that Dr. Bennett has permitted no operation where there were not gross indications of actual disease such as would compel urgent measures in the sane.

However it may be of some benefit to the profession to have this moot question definitely settled by the State Board of Charities and its legal member thus early in the investigation. We hope these authorities will not rest idly content until they have definitely settled, at least to their own satisfaction, the "illegality, the brutality, the inhumanity and the inexcusability" of cerebral surgery in cases of mental disturbances caused by old depressed fractures, tumors, abscesses and the like in the brain.

Perhaps it is true humanity to keep the irresponsible wards of the state intact in their insanity, but it is doubtful if even the *savants* of the State Board of Charities would hesitate to invoke any means of relief, even such brutal and inhuman ones, were the unfortunate victims closely reated to themselves.

THE BOARD OF HEALTH.

During the last four weeks the number of cases of diphtheria reported to the Board of Health has ranged from 144 to 154, and the deaths from 36 to 62 weekly. The Board has guarded more or less efficiently those houses in which the disease has had its victims. This has been a necessary precaution which should not have been suspended for a single hour, but it appears that on the 28th of December the Health Officer withdrew from the scenes of the disease all watchmen employed by the Board, for the stated reason that the appropriations for 1892 had been exhausted. On the following day, however, it was discovered that such was not the case, and, consequently, some of the watchmen were reinstated and the quarantine about the infected houses again set up.

That the quarantine was intermitted for a day or an hour was a mistake. The Health Officer, if the Board's treasury were really empty, should have given the watchmen personal assurance of their being ultimately paid, or he should have consulted the Mayor, who could have got in an hour subscriptions from citizens sufficient to pay for guarding every dangerous point. The Health Officer, in such an emergency, could have got the little money needed for a purpose so nearly affecting the health and lives of the community at the LEDGER office, or from any one of a hundred other offices near at hand, where it would have been willingly advanced or presented him. There was no valid excuse whatever for suspending the quarantine of the diphtheria cases for a day or an hour.

The large number of deaths which have occurred from this disease during the year past, the larger number of cases and the continued prevalence of the malady suggest that the Board of Health is not conspicuously competent to deal with a contagious disease which has got so strong a foothold and the mortality from which is so great.

The Board of Health proposed, and in its treatment of Philadelphia's commerce, used truly remarkable means to prevent cholera entering the city. Its quarantine policy and methods were, and still are, as antiquated, crude and clumsy as they well could be. They appeared to be intended rather for the crippling of commerce than for protecting the public health.

Take as an example of the practices of the Board its treatment of certain passengers on the Indiana the other day. On the last voyage of that ship three children developed scarlatina; they were at once isolated from the passengers in another part of the vessel, and given the best medical attention. No other cases had oc-

curred when the Indiana arrived at her dock on December 31st, nine days after the third and last case had developed.

But under orders from the Port Physician, by instructions of the Board of Health, the three children referred to, and all other members of the families connected with them, together with all the other children under twelve years of age aboard the ship, and all the other members of their families, were placed in ambulances, provided by the Board of Health, and driven through the cold streets to the distant Municipal Hospital, commonly known as the City's Pest House, and largely occupied at the time by diphtheria patients. All those persons were kept in this place of contagious diseases until January 4, when they were returned to the vessel. Prior to their removal to the hospital the steamship agents recommended to the health authorities that all passengers who were regarded as suspects should remain aboard the Indiana, where they could be isolated and receive the best treatment and attention, at the company's sole charge and expense, instead of being hauled through the streets to the pest house, but the offer was refused.

Inquiry made at the German, Jefferson, Philadelphia, Hahnemann, Jewish, University, Medico-Chirurgical, Pennsylvania, Presbyterian, Episcopal and St. Agnes's Hospitals shows that neither of these institutions receives diphtheria patients, and the Board of Health has ordered that all such cases shall be sent to the Municipal Hospital. In view of the fact that that institution has not the resources, facilities or appliances for treating the diphtheria in the most effective manner, and as the Port Physician, in a letter dated January 1st, 1893, stated that the city is "engaged in a desperate struggle with an epidemic of diphtheria," would it not be reasonable that some provision should be instantly made for treating aggravated cases of the disease, and also for providing a headquarters where poor patients, at least, could be promptly treated by the most skilled physicians? Why should there not be promptly established a diphtheria hospital? It will be noticed that, according to indisputable evidence, cases are commonly left to be treated in the place of their origin, be it a mansion or a small, crowded household of the very poor, and, even with such a condition of affairs, all possible physical restraint as to the intermingling of the inmates of the various houses in which diphtheria existed was removed for a time, as recently as Thursday, December 28th, 1892, through the removal of watchmen from quarantined houses.

Common sense would seem to indicate that, as Philadelphia has suffered during the last few months from what is designated by a prominent health authority as "a scourge of diphtheria," some steps should be taken to stamp out the disease, which is amongst us in visible form, rather than to concentrate the efforts of the Board of Health upon crude schemes to repel a no more dangerous scourge, which, it is only conjectured, may appear in our vicinity within the next four months. Not a single suspected case, even, of cholera, so far as is known, was brought to this port by any ship last summer.

A diphtheria hospital could be established at once, and, if placed under expert management, the funds to carry it on would not be lacking.

Meanwhile, the Board of Health should do something to show that it is entitled to public confidence. Its quarantine methods, as applied to ships or houses, are not of a sort to give assurances of its intelligent appreciation of what is best to be done, or how to do it.—(Ed. *Public Ledger*, *Jan. 10*, *1892.*)

Effect of Intra-nasal Obstructions on the Singing Voice.

Dr. A. B. Thrasher (*Cincinnati Lancet-Clinic*) says:

Intra-nasal obstructions are a common and serious cause of disorders of the singing voice.

Generally the obstruction is accompanied by an affection of the soft palate, and less frequently by pharyngeal and laryngeal disease.

When there is simple intra-nasal obstruction not complicated with palatal, pharyngeal, or laryngeal lesions, the timbre only of the voice is affected.

When the movements of the soft palate are interfered with, then the upper register and the soft medium register are affected, in addition to an injury to the quality of the voice.—*Am. Lan.*

NEW GROWTH OF THE UMBILICUS*

This interesting monograph contains many important communications, which have been derived largely from the surgical clinic at Halle, while a number have come under the author's personal observation.

The collection of 185 cases have been carefully studied and classified. This is the first of a series of studies on carcinoma which was inaugurated by the late R. Von Volkman, and begun by his assistant shortly before his death. Pernice classifies the case under four heads:

I. *The Inflammatory Processes of the Umbilicus.*—Under this head he recognizes five forms, namely: 1. A case of navel-granular. 2. A case of navel-gumma, (which had softened and thus had the appearance of a degenerating carcinoma.) 3. The navel concretions. 4. A case of a horny excrescence of the umbilicus. 5. Papillary fibroma, (these are placed under this head from the fact that they originate by a slow form of inflammation, the tumor developing slowly at its base.) These cases studied in detail will prove of interest.

The second chaper takes up:

II. *The Growths Originating in the Connective Tissue.*—Under this head Pernice reports: 1. Two cases of fibroma and fibro-lipoma. 2. Two cases of angioma. 3. Nine cases of myxoma. 4. Fourteen cases of sarcoma and fibro-sarcoma. Eight of these came under the author's own observation; among these he met with two cases of melanotic sarcoma.

The author has devoted more time and study to the third class making it especially interesting regarding the origin of the various forms of malignant growths. His classification is as follows:

III. *The Growths from the Umbilicus Originating in an Epithelial Basis, Particularly Carcinoma.*—Pernice separates the primary from the secondary forms and since the value of this essay concentrates itself in this chapter, it becomes desirable to enter into a little more detail regarding its theories. 1. Primary Carcinomas, under which he reports 27 cases, among which the following differentiations are observed: Cancroid, Papilloma degenerating into Carcinoma, Scirrhus, Tubercular Epithelioma, Colloid Carcinoma, Encephaloid Carcinoma. In the greater portion of the first three mentioned their origin can be traced to the superficial layer of the epithelium. The second growth is characterized by epithelium similar to that found in the intestines. The explanation for the frequency of Cancroid may be found in the chronic irritative condition met within the collection and decomposition of dirt and epithelial masses, hair, and sebaceous matter. Their growth is slow, frequently degenerating from papilloma, and partake of an abscess or papillomatous appearance. The prognosis is relatively favorable. It is advisable to operate early and never to remove a suspicious malignant growth without opening the peritoneum for careful inspection and removal of suspicious infiltrates. If the inguinal glands are enlarged they should be extirpated. Scirrhus, which should be treated from the same standpoint, derives in all probability its origin from the epithelium of the skin, perhaps the most deeply seated part of the umbilical cicatrix. It is characterized by its relatively rapid growth. The prognosis is relatively more unfavorable.

To the second group, whose origin is traced to the more deeply seated epithelium, belong the cases of Colloid and Encephaloid Carcinoma. Their epithelium resembles that of the intestine, and they are, perhaps, closely related to the ductus omphalomesaraicus. (A swelling of the umbilicus may often be regarded as primary when in reality it is simply a continuation from a deeper seated growth; for example, an extension from a cancer of the stomach). Rapid growth into the deeper structure is characteristic of this variety, extending not only through the umbilicus but also into the peritoneum and abdominal organs. On several occasions small carcinomatous growths were observed through the peritoneum and upon the serosa of the liver. Frequently infiltrations have been noticed extending from the umbilicus to the liver, to the bladder,

*Translated from the Central. f. Chirurg, No. 41. 1892, for MEDICAL and SURGICAL REPORTER.

in the suspensory ligament of the liver and the median vesical ligament, carried, no doubt, by the lymph channels. The inguinal glands were frequently found infected, but infection was rarely noticed in the retroperitoneal glands and never in the axillary glands. The prognosis is unfavorable.

2. Secondary Umbilical Cancer.–Of this variety he reports twenty-nine cases; twenty among women, nine among men. The primary lesion was usually somewhere in the abdominal organs—stomach, uterus or intestines. The ages ranged from 33 to 73 years; the greater number of cases were found between the ages of 50 and 60. All cases ended fatally in spite of numerous operative procedures. The growths were a sequence to the continued progression of the disease in twenty-four, and in five it appeared as a metastatic formation.

In the first series of cases reported under this head, ten cases were described, in which there was direct adhesion of the cancerous mass to the umbilicus; thirteen where communications could be traced from the ligamentum suspensor hepaticus, and lastly, a case in which it followed the incarceration of a carcinomatous nodule of the omentum in an umbilical hernia, the primary growth having started in the uterus. The first ten cases were for the most part secondary manifestations of a primary cancer in the stomach, or an omental metastasis, cancer of the gallbladder or intestines, which had become adherent to the umbilicus. Among the thirteen cases the primary affection in seven was of gastric origin, one of the intestine, two of the uterus, three of the peritoneum generally.

The metastatic formation of cancer in the umbilicus is rare if not in direct communication with the lymph channels, it seemingly being necessary to have a direct medium of interchange. The prognosis is unfavorable, operative interference having in all cases been hopeless from the extensive infiltration.

In a third group under the third class he places:

3. Atheroma and Dermoids of the Umbilicus.—He reports twelve cases. The treatment and its result is precisely the same as in other parts of the body.

Under the fourth class the author places:

IV. *Adenoma and Enteroteratoma of the Umbilicus.*—They apparently simulate the granuloma and are connected with the ductus omphalomesaraicus. Thirty-eight cases gathered from the literature and one case under personal observation are reported. Histologically, they are composed of two layers, a peripheral glandular layer and a smooth, muscular layer, and occasionally a thin, central connective tissue layer could be observed. The author does not approve of the names given this form of enlargement, since he is of the opinion that, generically speaking, adenoma does not express its mode of origin—not being a new growth—but a prolapsed diverticular portion of the tissues, and for that reason enterateratium is equally unsuited to describe it. The author, therefore, proposes the name of diverticular prolapse of the umbilicus, which explains the nature of the swelling and its peculiar histological construction.

A Case of Poisoning of Methylblue.

An engineer was suffering from a typical attack of malarial fever and was treated with arsenic and quinine without success; received some benefit from the use of strychnia. After consulting another physician later he ordered methylblue, three or four times daily 0, 2 grm. On the second day there was difficulty of urination and vomiting; notwithstanding this he continued taking the medicine. In the following few days these symptoms increased; urination became more painful accompained by some bleeding. After six days the treatment was stopped and the symptoms of poisoning disappeared in a few days.—(*Wein. Aerztl. Centr.-Anz.*)

The Treatment of Tetanus.

Verneuil believes that the practice of Berger of amputating the affected member becomes useful in a relatively small number of cases since the results are not certain and the most favorable time for operation is not always known; and lastly, that the excitement preceding the amputation, as also the administration of anæsthetics, may produce a fatal attack of tetanus. Verneuil in order to support this statement cites six cases in which amputation resulted unfavorably. Among these, three in which the operation was performed be-

fore a distinct attack of tetanus had set in. Chauvel also regards amputation as a questionable treatment for tetanus.

Vaillard could never cure artificially induced tetanus in an animal by amputation. Of greater importance is the rigorous antisepsis of the wound, since the investigations of Vincent and Vaillard have proven that the microbe is only active when in contact with other septic microbe (Staphylococcus and Streptococcus.)

Trasbot called attention to the fact that the prognosis of tetanus in the horse, is more favorable if its duration extends over a period of two weeks. It has also been noticed that chronic tetanus in the human being is more benign than the acute. For that reason greater importance must be placed upon therapeutic treatment.

Labanc declares that the results which Nocard has attained with antitoxin in chronic tetanus would have been healed as well without it. He considers the injections injurious, for the reason that antitoxin produces, like all other toxins, an exacerbation of the disease with fever which may induce a return of the tetanus symptoms.—(*Bull. Méd.*)

ABSTRACTS.

CORRECT GYMNASTIC POSITIONS.

Prof. Hans Ballin, (*The Annals of Hygiene*, December 1892,) says:

It is one of the main requirements in gymnastic work that a position should be correct. A carelessly executed exercise is of little or no value and leads often to the contrary of what is aimed at. He who practices gymnastics unsystematically, or he who teaches with a point in view to attain certain exercises and feats independently of position and posture of the whole body, gives evidence that he has not conceived the right spirit of physical culture.

We meet, however, with the fact that many gymnasts who exercise at random in the gymnasium or at home, or indulge in some manly sport, pay little or no attention to the execution of the movement as long as they have carried their point. They will jump and are proud when they can clear the rope at sixty inches, and they care very little that they did so in the most ungraceful manner. They will perform a giant swing on the horizontal bar, having their feet wide apart, keeping their body flabby and without any vigor and attitude, which does but little to develop muscular control. Now there may be some who claim that it matters very little how a man jumps as long as he exercises his body, and if he ever succeeds in jumping to an enormous height, he will be nevertheless the champion jumper. A man who will dare and accomplish the giant swing, will undoubtedly be considered by his comrades a daring fellow, who outdoes them completely.

This is all true, they will be the boys who will find their admirers. But physical exercise aims at more than to become a champion of feats; it must educate the body so it will be the servant of its supreme master—the mind; and, futhermore, must develope the human form symmetrically. This can only be attained by paying strict attention to the position and carriage of the whole body while performing physical work. An exercise which requires principally the action of the muscles of the legs is of little or no account when the trunk and arms are in an uninteresting and careless posture.

Experience teaches us that it takes a long and tedious course of practice for a person to become master of all groups of muscles in order that he will he enabled to move them at instant command. Complex motions make it still more difficult for co-ordinate action.

An untrained gymnast will lay all stress on the main features of the exercise, and having accomplished this is unconscious of the appearance and correct execution. A boy who tries for the first time to climb a ladder, going hand-over-hand on the underside of it, will sprawl with his legs like a frog out of water.

It can often be proven that these champions of some athletic or gymnastic sport act surprisingly and clumsily when they try for the first time to execute some simple calisthenic movement. An exercise correctly taken must at all times be an exercise of the whole body; there is somewhere an obstruction, which must be

overcome by practice. These hindrances to the performance of an exercise indicate the probability that the teacher has advanced too rapidly or unmethodically. The method must aim to conduct the scholars through the consciousness of bodily evolution by practice to the unconscious action. The more a person is lacking control over his muscular system, the more is he liable to bring into action, unnecessarily, those muscles which it is easiest for him to govern. If he, therefore, had to exercise with his legs, and has better command over the muscles of the arm, they will do the unnecessary movements, which make a person's actions awkward in appearance. This awkwardness is most effectually fought by laying stress on the carriage and posture of the whole body, thus recognizing the truism that the whole muscular system is an unbroken tissue, one muscle is closely allied to the neighboring one, and all are supplied from a common nerve-centre.

CLUB FOOT.

Dr. Rœckel, in the *Australian Medical Journal* for November, 1892, in relating some surgical experiences at the National Orthopædic Hospital, London, says that the traditional treatment for club foot is divided into so many stages, generally only two. Say a baby is brought into the hospital with talipes equino varus of long standing origin. Here the stages in the treatment will be two—the first, the removal of the varus, the second, that of the equinus. Say a case is complicated by what is called plantar varus, that is, contraction of certain portions of the plantar fascia, and of the long calcaneo-cuboid ligament. Here, the first stage will be the removal of this deformity; the second, the removal of the varus due to the shortening of the tibialis anticus or posticus, or both; the third, that of the equinus. This dividing the treatment into stages simplifies matters wonderfully, and ensure good results in the end. It rests too on a scientific basis, as well as a practical one.

As operative measures in true orthopædic surgery consist only in the subcutaneous division of tendons, fasciæ and ligaments, they may be said to play but a small part in the treatment, though often, of course, their *rôle* is important enough. The main treatment, the backbone of the curative procedure, is unquestionably the working or manipulating of the affected part after operation, or even without it.

Well, we will suppose now that a mother brings her child, say but a few months old, with a congenital talipes equino varus. The first point is to ascertain whether the varus will require operation, that is, division of the tibialis for its removal. This is very easily done, nothing more easy in the work. You simply try with the hands whether you can force the baby's foot straight, that is, into a position free from varus. If you can, no operation will be required; if you cannot, you will have to divide the tibialis, one or both. For if you are able at the first interview to overcome the varus with the strength of your hands, it is an absolute certainty that working will remove the deformity. This is a grand axiom in orthopædic surgery, a very grand axiom.

Whatever improvement you can effect by manipulation for a few seconds, will become permanent by repeated and prolonged manipulation. We will suppose now that in the baby's case just mentioned, you find yourself to overcome the varus by your hands, the baby will then have to attend daily at the hospital to have its varus worked out by the nurse for a week or two, the mother of course bringing the child and receiving her lesson as to the manipulation which she will have to continue at home so soon as she gives the nurse proof of proficiency. You will see how excellently this plan works. It is naturally a great bother for the mother to bring her baby daily to the hospital, especially if she lives far off. She will therefore exert herself to the utmost to learn her lesson in the shortest possible time. The nurse on the other hand, knows that at the first visit to the surgeon after the mother is officiating as worker, she will be put through her paces, that is, made to work her baby's foot in his presence and before his eyes. Nurses, as you are all aware, do not like snubs, and something more than a snub to the nurse would

follow a mother's inefficiency in the working department. Is it difficult to work out the varus from a baby's foot? No, certainly not. You grasp your fixed point, or rather the point you mean to fix (the heel) firmly with your left hand; with your right you lay hold of the lower end of the foot about opposite the heads of the metatarsal bones, and then give a series of jerks outwards, that is, in the opposite direction to which the varus tends. Of course, an experienced worker will make much more headway than a beginner as to result, still a baby's foot is so small, the resistance to be overcome is so comparatively slight, that mothers, unless indeed they should happen to be the very greatest of geese, can manage to work out this deformity in from a fortnight to five weeks.

THE STORY OF THE INSANE.

Dr. Wells, in an inaugural address delivered before the Minnesota Academy of Medicine, Nov. 2, 1892, says in part: "In the light of what has been and now is, no state will ever permit its insane poor to be remanded to the mercies of the poor house. A generous and enlightened policy alone becomes the dignity and honor of every state in its provision for the insane. Their numbers are rapidly accumulating, and in no other way can their pressing needs and those of common humanity be satisfied. They are the most helpless and defenseless of all God's creatures, and the most dependent upon those whose reason has been spared and without which life is nothing worth. The insane are not only the wards of the State but above all of the medical profession. Through their long wanderings has the medical profession been to them a cloud by day and a pillar of fire by night. Before the influence of the new pathology prejudice and superstitions have faded away. Ever their defenders they have stood inflexible between them and the injustice of courts and juries and saved them from the hangman's knot.

One hundred years ago five hundred insane were chained in a single asylum under the lash of cruel keepers and visited twice a week by an apothecary. Now is our triumph complete as we behold the insane throughout the world in perfect trust, committed to our care. The mission of the medical profession has ever been and is to be the benefaction of mankind, and we may be justly proud of the part we have borne in this great and enduring work of reform in the affairs of the insane, for there exists no grander monument to the world's enlightenment and progress than the redemption of the insane from their centuries of bondage."

EXTRA-UTERINE PREGNANCY.

At a meeting of the Gynecological Congress, at Brussels, September 16, 1892, (*The Provincial Medical Journal*, October, 1892), A. Martin, of Berlin, read a paper on this subject. His conclusions were: 1. The etiology of extra-uterine pregnancy remained, to the present day, veiled in the deepest obscurity. Certain hypotheses already advanced only explained isolated cases in a manner which did not defy criticism. The question could not be settled until the physiology of impregnation was better understood. 2. Most frequently the ovum was implanted in the tube. Ovarian attachment was less rare than recently supposed. Abdominal insertion of the ovum remained doubtful. 3. The diagnosis of ectopic gestation was a diagnosis of probability, except in cases where we could observe the development of the fœtal sac outside the uterine cavity, or the development of an intra-uterine decidua without any distinguishable chorion, or when we discovered the fœtus itself. 4. The evolutions of extra-uterine pregnancy rarely ended in retrograde metamorphosis (lithopædion mummification) without any intervening accident. As a rule, the death of the ovum occurred through hemorrhage into the fœtal sac, or into the ovum itself. The blood escaped into the abdominal cavity, either out of the ostium of the tube (tubal abortion, properly so called), or by rupture of the

tube, in its continuity, into the peritoneal cavity or broad ligament. The hemorrhage only ceased in exceptional cases. In most instances death occurred either from anæmia or from a peritonitis, the precise nature of which remained obscure. Ectopic gestation should always be reckoned as a dangerous neoplasm, and treated accordingly. Cases of development to term were so rare that to respect the interests of the child was to neglect totally those of the mother. 6. Consequently, it would appear that operative interference, undertaken as soon as possible, was the right course in all forms of ectopic gestation. The fœtal sac should be extirpated if possible. Treatment by hypdermatic injections of morphine cured very slowly. Treatment by electricity could not yet be rated at its true value, as hitherto recorded observations on this method were not above criticism.

A CLINICAL STUDY OF GLANDERS IN THE HORSE.

Discussing this disease, Dr. W. H. Daly says (*Med. Record*):—In the teachings of the books, the names glanders and farcy are synonymous, but with the usual loose use of terms by the more ignorant and would be veterinarians these names are applied to two different phases of glanders, with the implication that they are two different diseases. That form of glanders where the nasal discharge is most prominent is spoken of commonly as glanders; the term farcy is used to designate the other form, where the disease displays lumps in the line of the lymphatics, along the belly and insides of the thighs, along the neck and elsewhere, varying from the size of a hickory-nut to that of a small apple, together with œdema of the legs and stiffness of the joints; later, the nodular lymphatics, or so-called farcy buds, break down and ulcerate; this form is spoken of as farcy, but it is all the same glanders, as syphilis that attacks the glands is none the less syphilis.

The nasal discharge in glanders is not necessarily offensive, and in most of the cases I have seen not at all so. When the animals are kept as clean as possible, moreover, the nasal discharge is not necessarily purulent, but may be of a starchy character, and may be chiefly from one naris.

The disease may lurk and be masked in the system of a horse for many months, and the only significant or apparent symptom may be a slight and inodorous discharge from one naris on driving the animal.

The horse may be far advanced in the disease, and with the discharge considerable, when the amount he may blow from his nose in driving is taken into account, e t so far as his apparent activity, spirits, and appetite are concerned nothing unusual may seem wrong, other than the evidence of a slight cold, or epizootic, with concomitant or following loss of flesh.

The disease has been known to have apparently disappeared in a given animal, the usual discharge to disappear, flesh return, nodular lymphatics or farcy buds to disappear by absorption, and later, from overwork or exposure to cold, the disease may return and pursue a fatal course.

That glanders is highly contagious, both to horses and the human being, there can be no doubt; yet in the stable of a friend, some time ago, two carriage horses were affected with glanders, while a third horse, that occupied a stall between the diseased horses and was in constant touch with them and drinking from the same buckets, was not affected, and is yet in good health. The glandered horses were destroyed.

While inspecting the nares of one of my equine patients, after using the nasal douche on him, I had on two occasions the misfortune to receive some of the mucous blown by the horse from his nares into my eyes and about my face. A careful washing and disinfection was at once resorted to, without any untoward event following.

I give these points as of some practical value, to counteract the vague and foolish terror that is inspired by the very name or suspected existence of glanders.

Let me give you a clinical picture of a typical case.

Horse twelve years old, fifteen hands high, weight probably eleven hundred pounds, dark brown, cob build, very high spirited, and of high intelligence and breeding—an animal of rare qualities and great endurance. This horse had for some

months a short hacking cough, that I jocularly denominated an old man's cough. He also had for several months a starchy discharge from one naris after being driven.

About January, 1892, we had an endemic of la grippe in the human population of Pittsburg, but there was no unusual amount of sickness among horses. This patient was not in good condition, however, and was losing flesh, but was spirited and active. One cold day in January, I rode him under saddle to the West Penn Hospital and back, a distance of six miles. The horse was spirited and anxious to go, and I indulged him, bringing him back rather warm, and instead of rubbing him dry, as I directed, the groom let him stand in a draught, while he turned the hose on his legs to wash the mud off, and then put him in his stall without a blanket, and without rubbing his legs dry. The next day the horse seemed excited and nervous, but not otherwise the worse for his ill care and treatment. A few days later he exhibited further evidence of cold; nose running copiously, cough, fever, pulse sixty, and limbs stiff. On examination there were revealed a few small lymphatic nodules along the belly in two direct lines backward from his forelegs; also some nodules along the crease in the neck above the windpipe. Yet the horse ate well and seemed to have usual good spirits; the nasal discharge was inodorous, but copious from the left naris, the mucous membrane of which was swollen, turgid, and of a dark pink hue, but there were no chancres on it; the mucous was now tinged with blood. This was about the eighth day after the severe ride and the maltreatment by means of the cold water and exposure.

The medical treatment at this time consisted of hot bran-mashes, with saltpetre, quinine, carbonate of ammonia internally; antiseptic nasal douch, followed by iodoform insufflations twice daily. There was little change in this condition for six weeks, when the legs began to be œdematous, and there was lameness, especially in the left hind leg, which was increased to twice the natural size by œdema. The farcy buds were now firm and hard, and as large as walnuts along the belly line and the nasal mucous membrane was swollen, and small, punched-out, chancre-like sores appeared in the left naris; the discharge was lumpy and thick, but inodorous, though very considerable, and the box stall was spattered all about each morning with bloody mucous of a gelatinous character, and very elastic and adherent to whatever it attached itself.

A few days later after the douche there was a copious and alarming hemorrhage of venous blood, which was arrested by elevating and tying the patient's head high up. In a week later the chancrous sores in the left naris were more numerous and quite characteristic of glanders; in fact, all the salient features of the disease were now present in undoubted character. The patient's appetite was normal, and the spirits were fair, though the emaciation was pitiful to behold. There was some arrest of the urinary secretion for a day or two, which was restored by the exhibition of rosin and saltpetre. The administration of arsenic, quinine, and iron was substituted for the other medicines, the cough and fever having abated; the copious nasal hemorrhage had occurred several times in the past week; once the amount was over two quarts, and was only arrested by a hot solution of alum, used as nasal douche.

Several of the lymphatics in the throat and neck were now in the eighth week about the size of a small apple, hard and well defined but not tender to pressure; the left nostril was enormously swollen, and studded with glanderous chancres that had sharp edges and gray bottoms resembling the true chancre as seen in primary syphilis; there was no odor that could be considered offensive, but the patient was kept as clean as possible, and great care was observed in every way.

I now gave arsenic, iron, and quinine in large doses, estimated as though I was treating a twelve or thirteen hundred pound man, and after a week further there was an abatement of the naso-pharyngeal symptoms, and the discharge became more distinctly purulent; the animal seemed better, and his coat, which had never stared or become rough but merely dull, looked better and somewhat glossy; his eyes, which for a few days previously were listless, were brighter.

Now, having had a full and very complete opportunity to study the disease in all its phases, so as to be able to recognize

it again, even in its earlier stages, I decided, although the animal was now improving, to destroy him, as I was obliged to absent myself from home, and there was rumored danger of the authorities proceeding against me. I accordingly had the horse shot. The post-mortem revealed extensive chancres of the nasal mucous membrane, from the size of a ten cent piece to the size of a silver dollar; the bones of the nose were denuded, and yet, at the bottom of several of the chancres repair had already begun on the edges of some of the sores.

Now as to prophylaxis. Complete isolation should always be resorted to, and if it is summer, the patient is better in an out enclosure or box-stall completely isolated.

For disinfection of premises after glanders, if the structure is too valuable to burn, first scrape all the wood where discharges have been lodged by being blown from the patient's nose; burn these, then wash all down with a rough broom and a solution of sulphate of iron (two pounds to one-half gallon of water). After this close the place tightly and burn sulphur in it for several hours. After this whitewash with a solution of fresh burnt lime, with a pint of crude carbolic acid, and a pound of sulphate of iron to the gallon of wash, flushing all crevices and corners. If this is done thoroughly there will be little or no danger to animals who occupy the premises subsequently.

Soak the blankets, if valuable, in a solution of corrosive sublimate, 1 to 500 and afterwards wash and boil them. Currycombs, brushes, and other tools should be scrubbed in hot water and soaked in a solution of corrosive sublimate 1 to 500. Harness can be washed in rather warm water, then rinsed in a sublimate solution and afterward rinsed in clear water and cleaned with a carbolic or mercury soap for a few times; care should be taken to eliminate from all the corners about the buckles and keepers any dandruff from the diseased animal.

The all-important question in glanders is to be able to recognize the early manifestations of the disease. This is exceedingly difficult, as the conditions are so masked, but from my observation I should say, where an animal has certainly been exposed to contagion take the best of care of him in every way, and observe the strictest cleanliness, and if later on you observe a persistent but very slight discharge from one or both nares, and some even slight lymphatic nodules along the belly-line of lympatics, from the size of a coffee-grain to a hickory-nut, these are the so-called "farcy buds," which when once felt can never be mistaken. If there is in addition a slight fever, put your horse on good alterative tonics and isolate him, but do not ruthlessly destroy him.

As an experiment I expose a young horse to the contagion, and at a time when he was suffering from colt distemper. The glanderous disease went on to development of farcy buds, slight nasal discharge, and temporary loss of appetite. The symptoms under the above alterative treatment all disappeared in less than two months, and the horse was in an improved condition[1] and although he is now receiving no treatment is, beyond doubt in my mind, safely in a sure convalescence, barring no accidents that will deteriorate his general health.

As to character of the disease I am of the opinion it is of a specific character, that is, contagious through its peculiar bacillus malleis, and that it is to a certain unascertained degree curable if taken early and properly isolated.

But I repeat herein lies the difficulty, viz., an early recognition of the disease. I would not by any means advise the purchase of a horse who upon a little active exercise runs a little starchy mucous from the naris or nares and has some hard nodular kernals like a pea or chestnut in the cellular tissues under the skin along the belly in a line with the forelegs; these are among the earlist objective constitutional symptoms, and I regret to say when present are often so masked as to escape notice of any other than an expert observer.

This is a clinical picture of glanders as I have personally observed it, and without regard to the teaching of the books, and I have given it to you, hoping that it may interest you not only in preventing the disease in those noblest of the lower animals, but also in the human being, who is so liable to be attacked by means to contagion.

1. Three months later this young horse is in fine condition and, so far as I can discover, in perfect health.

THE LIBRARY TABLE.

Notes on the Newer Remedies and their Therapeutic Applications and Modes of Administration. By David Cerna, M. D , Ph. D. Demonstrator of Physiology in the Medical Department of the University of Texas, etc., etc. Philadelphia, W. B. Saunders, 913 Walnut Street, 1893. Price $1.25.

The author has endeavored to furnish the practitioner and student, in as brief a manner as possible, the salient points in the employment of the newer drugs in the treatment of disease. Such of the drugs as are not yet fully studied therapeutically, are given only a passing notice. The book will be useful to the student or practitioner who, without neglecting important matters, can keep abreast of the times in the science and art of modern therapeutics.

Acne and Alopecia. By L. Duncan Bulkley, A. M., M. D., Professor of Diseases of the Skin, New York Post-Graduate Medical School; Physician to the New York Skin and Cancer Hospital, etc. Published by Geo. S. Davis, Medical Publisher, Detroit, Mich. Price, postpaid: Paper, 25 cents; cloth, 50 cents.

The author presents these diseases in a clear, concise manner. No attempt is made to exhaust the subject, nor are references made to authorities. The desire has been to present the conditions as they appear to one daily engaged in relieving them. The author's reputation as a practitioner, is sufficient guarantee of the book's usefulness.

Gonorrhœa and Urethritis. G. Frank Lydston, M. D. George S. Davis, Detroit, 1892.

The author of this valuable little book has succeeded in getting a vast amount of information in its pages. His views as regards the pathology and treatment of gonorrhœa are distinct and practical. He does not advocate the abortive plan of treatment, claiming it a relic of by-gone days.

The work abounds in useful suggestions. To the physician who desires knowledge in the treatment of Genito Urinary Diseases this little book will be a welcome mentor.

The Students' Quiz Series. Edited by Bern B. Gallaudet, M. D., Demonstrator of Surgery, College of Physicians and Surgeons, New York. This new series of Manuals in form of question and answer enjoys the unique advantage of issue under careful editorial arrangement and supervision. The Editor, himself an experienced practitioner and teacher, has assigned the various volumes to well-known specialists and instructors in New York. The thirteen volumes cover the subjects essential to a thorough knowledge of medical science and art, and they may be trusted as authoritative and abreast of the times. They are of value not only to students and teachers, but to practitioners who may desire to recall details for instant use.

The large utility of this series therefore assures an enormous sale and justifies a very low price in proportion to intrinsic value.

Anatomy, Brockway, F. J.; *Physiology*, Manning, F. A.; *Chemistry and Physics*, Struthers, J.; *Histology, Pathology and Bacteriology*, Beach, B. S.; *Materia Medica and Therapeutics*, Warner, L. F.; *Practice of Medicine*, Doubleday, E. T.; *Surgery*, Sands, R. A.; *Genito—Urinary and Venereal Diseases*, Chetwood, C. A.; *Disease of the Skin*, Ransom, C. C.; *Diseases of the Eye, Ear, Throat and Nose*, Miller, F. E.; *Obstetrics*, Hoyt, C. W.; *Gynecology*, Bratenahl, G. W.; *Diseases of Children*, Rhodes, C. A.

So far as works of this nature can be of use these compends answer the purpose of their publication. Lea Bros. & Co. being the publishers is sufficient guarantee of the superiority in this class of medical books.

RECENTLY RECEIVED.

Fermentation, Infection and Immunity. A new theory of these Processes. By J. W. McLaughlin, M. D., Austin, Texas, 1892. Price 2.50.

Hand-book of Massage. By Emil Kleen, M. D., Ph. D., authorized translation from the Swedish, by Edward Mussey Hartwell, M. D., Ph. D. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1892. Price $2.75.

A Manual of Clinical Ophthalmology. By Howard F. Hansell, M. D., and James H. Bell, M. D. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1892. Price $1.75.

A Hand-book of the Diseases of the Eyes and Their Treatment. By Henry Swanger, A. M., M. B., F. R. C. S. I. Fourth edition. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1892. Price $3.00.

Transactions of the Homeopathic Medical Society of Pennsylvania, 1892.

NOTES.

Dr. Nicholas Senn, of Chicago, is now preparing a "Syllabus of Lectures on the Practice of Surgery" arranged in conformity with the "American Text-Book of Surgery, which will be a valuable aid to all who have this great book.

Moullin's Text-Book on Surgery was first published in April, 1891. So favorable was its reception by the medical profession and press that in a little over twelve months it was recommended at more than twenty medical Schools, and the large edition that had been prepared was exhausted. So much for past history.

Early last summer Blakiston, Son & Co., were fortunate in securing the services of Dr. John B. Hamilton, formerly Surgeon-General of the Marine Hospital Service, now Professor of Surgery at Rush Medical College, Chicago, as editor for a new edition. He has now almost completed his work, and within a short time they expect to place before you the book generally revised so as to represent Surgery as it is to-day, with a number of new and beautifully colored illustrations printed in with the text.

"Our claim that Moullin's Surgery is the best text-book for the student, and general work of reference for the practitioner is based upon the reviews of a large number of journals that have pronounced it eminently practical, and upon the fact that so many teachers have seen fit to recommend it. But beyond this we may say that broad principles are stated in a clear, authoritative manner, that the relative value of the different subjects has been carefully considered, and that about the whole there is an air of responsibility that renders plain the fact that the author knows whereof he speaks, not only from his own experience, but from an acquaintance with American and foreign literature. There is also a uniformity of style, an elegance of diction, that attracts and interests the reader, while it makes plain the subject under discussion."

Public Opinion, the eclectic weekly, of Washington, D. C., which has made a feature of offering liberal cash prizes for the best essays on prominent topics, has just announced three cash prizes of $150, $100, and $50, respectively, for the best three essays upon the question "What, if any, changes in the present immigration laws are expedient?" The contest is open to any one and full particulars may be had by addressing *Public Opinion*, Washington, D. C.

The "American Text-Book of Surgery," edited by Professors Keen and White, of Philadelphia, is pronounced a success. It has been adopted as a "Text-Book" by leading Medical Colleges and Universities. Nearly five thousand copies have been placed in physician's libraries, and every indication points to a sale of at least as many copies more in the next six months.

CURRENT LITERATURE REVIEWED.

THE ANNALS OF HYGIENE.

The opening article of December's issue is Prof. Ballin's on "Correct Gymnastic Positions," of which we give fuller note elsewhere. Under the title of "Hunting Health and Bears" Dr. Reed, of Ohio, gives quite a lengthy description of the hygienic advantages obtained by those who, weary and worn out by the duties of an exacting practice, or from the daily wear and care of a humdrum business life, have their vitality exhausted and seek to regain it by spending a vacation in the Rocky Mountains "hunting health and bears."

"Secrets of Health" by Dr. Parker and "Sanitary Day" by Dr. J. F. Edwards about finishes this month's issue.

THE JOURNAL OF NERVOUS AND MENTAL DISEASES.

The only article of any importance in December's number is one on "The Equitable Responsibility of Inebriety" by Dr. Wright. Dr. E. P. Hurd has a translation of Professor Charcot's paper "Vibratory Therapeutics"—the application of rapid and continuous vibrations to the treatment of certain diseases of the nervous system. These two articles together with Dr. Field's paper on "Othæmatoma" comprises all that is of any importance in this month's issue.

ARCHIVES OF PEDIATRICS.

In looking over the list of collaborators, forty-eight in number, which is given a prominent place and which contains the names of men who have devoted a life time to the subject of Pediatrics, and then turning to the table of contents and glancing over the list of original communications one is amazed at the meager exhibition—four papers, three read before the American Pediatric Society last May, the other read before the American Orthopædic Association in September.

COLLEGE AND CLINICAL RECORD.

The Dec. "Record" contains only two papers of any note. "The Puerperal Sepsis," by Dr. E. E. Montgomery, and "Urethral Irritation" by Dr. Mary Jacobi. We trust that this journal which has had an existence of thirteen years will commence its next year by putting its table of contents in a place that its subscribers can find, without having first to read its articles and advertisements.

THE PHILADELPHIA POLYCLINIC.

The "Polyclinic" announces in its December number, that beginning with January, 1893, it will be issued monthly instead of quarterly as heretofore.

Dr. Crozier Griffith has an interesting lecture on "Diagnosis of the more frequent Organic Heart Murmurs." "The Prophylectic and Palliative Treatment of Fistula in Ano" by Dr. Lewis Adler, Jr., is the more important paper.

INTERNATIONAL MEDICAL MAGAZINE.

The December issue appears with eleven original papers, four of which were read last June before the American Climatological Association. Dr. Eli Long has a paper on "Physiology of the Respiratory and Circulatory Changes at Birth as related to Asphyxia and its Treatment." A particularly good article is a Clinical Lecture of Dr. Hulke, of Middlesex Hospital, London, on "Aneurism." Possibly mention should be made of Dr. Dewey's "Study of Insanity following the Keely treatment for Inebriety." The doctor is inclined to think that this treatment consists of a medication of well-known tonics and perhaps cathartics combined with some narcotic or mydriatic drug, probably atropine, together with the powerful influence, mental, with which the patient is surrounded. Dr. Keely to the contrary notwithstanding denies in toto the uses of narcotics.

UNIVERSITY MEDICAL MAGAZINE.

Dr. Daland's article "A Clinical Study of Eleven Cases of Asiatic Cholera treated by Hypodermoclysis and Enteroclysis," is given first place in January's number. This paper is the result of a very careful study of the clinical history and treatment of Asiatic Cholera. These observations were made at the Swinburne Island Hospital in New York Bay last September.

"Mydriatics in Ophthalmology," by Dr. Risley, is given second place. In considering these drugs the doctor states that it is, first of all, important that the solutions of the salts of the alkaloids in use should be bland, since any irritation of the tissues is especially harmful and directly opposed to the purposes for which the drug is usually employed.

Dr. Sinkler's paper "Insanity in Early Childhood" completes the articles of interest in this number.

PERISCOPE.

THERAPEUTICS.

Peroxide of Hydrogen in Gastric Disturbances.

A. N. Iakovleff (St. Petersburg Inaugural Dissertation, 1892, No. 109) has made nine experiments on eight subjects, of whom some were suffering from chronic gastritis, some from nervous dyspepsia, one from cancer of the stomach, and one from hyperacidity of the gastric juice, while the eighth was healthy. In all but two cases the patients were given 4 c. c. of a three-per cent. solution of H_2O_2 before breakfast, dinner, and supper. The patient with malignant disease and the one with hyperacidity took a two-per cent. solution, 4 c. c. from three to six times a day. The following is a summary of the results of these experiments: (1) Under the influence of H_2O_2 the general acidity of the gastric juice and the proportion of free HCl invariably increase. (2) The proportion of lactic acid always decreases, while in later stages of digestion the acid disappears altogether from the gastric contents. The phenomenon should be attributed to the well-known antifermentative properties of H_2O_2. (3) The digestive power of the gastric juice is markedly intensified. (4) In the case of hyperacidity (as well as in another similar case in the author's private practice) the administration of the peroxide was followed by a distinct aggravation of all gastric symptoms, while in all others, including that of cancer, marked improvement was observed, the appetite improved, the epigastric pain ceased, eructations and vomitings decreased or entirely disappeared, the bowels became more regular, etc. The author further made experiments on frogs and dogs, his object being to elucidate the effects of H_2O_2 on the circulation. The results agree pretty closely with those published by Guttmann and Schwerin, the essential point being that H_2O_2 is decomposed by the blood, and hence can give rise to gaseous embolism with its consequences, such as dyspnea, dilatation of the cardiac cavities, etc. From these facts, Iakovleff concludes that injections of H_2O_2 into the circulation for therapeutical purposes, as suggested by some authors, are absolutely inadmissible.—Brit. Med. Jour.

The Simplification of Therapeutics.

The day of a more precise, hence more scientific application of remedies in the management of disease is dawning. Polypharmacy is the offspring of that mysticism with which our forefathers were wont to surround themselves unconsciously. In all other phases of human endeavor a spirit of inquiry is abroad; the devout churchman even asks questions to-day which a few decades ago he would have deemed sacrilegious to entertain. He does not on that account lose aught of the true essence of religion; but he satisfies his reason as far as is consistent with his faith. We cannot marvel, therefore, if the doctor's clients often want to learn something of the agencies resorted to in combating an enemy supposed to reside within them.

The multi-pharmaceutical prescriptions we give him are not open to his comprehension; indeed candor would oft compel the prescriber himself to acknowledge a lack of rational appreciation of the objects and aims of his medication.

It has come, about, therefore, that the latter has become more simplified. The shotgun prescription of a former epoch is now rarely seen. The trend of teaching now is in the direction of the rationale of remedies. Thus the student becomes less slavish in his adherence to formulæ because he understands better the principles underlying the action of their component parts.

We may learn a valuable lesson on the Evolution of Simplified Therapeutics, and its enormous value, from the surgeon. When antiseptic surgery first astounded the filth-ridden surgical world, the minutiæ of spray, gauze, protective, etc., seemed absolutely necessary to success. We discover now that poly-antisepsis is unnecessary; that the chief element of true antisepsis is asepsis or cleanliness. The scrupulous, unflinching, searching and skeptical cleansing of the field of operation, of the operator, and of the wound, proves today to be the source of the most brilliant surgical statistics. Dr. C. Schimmebusch, upon whom devolves the preparation of cases for the most renowned surgical clinic in Germany, considers "boiling water as the most powerful of all disinfecting agents." He says: Instruments are best sterilized by boiling in a one-per cent. watery solution of carbonate of soda for five minutes, the soda increases the sterilizing power of boiling water, because it removes all fatty material and prevents rust. What is this but plain, unvarnished cleanliness. While this evolution to the simpler, hence higher, type of treatment is going on in the brilliant field of surgery, let the physician draw lessons of value from it. May we not by simplifying medication, by boiling down, as it were, our formulæ to active therapeutic entities, by eliminating mystical, inexplicable methods, and holding fast only to simple, rational, demonstrable therapeutic agents, do as much for internal disease as the surgeon has done for the palpable or external. It is a consummation devoutly to be wished; it must come in good time. In the meanwhile the sick are languishing or dying under our ministrations. "Let us be up and doing." Who shall be the Lawson Tait of Internal Medicine? The man who is bold enough to combat the prejudices of the most prejudiced middle class—the medical practitioner.—Gail. Med. J. Edit.

Cocaine Antidotes.

S. Mitchell (Medical Record) has found that while ammonia, digitalis and brandy will relieve the milder toxic manifestations of cocaine poisoning, they signally fail when these symptoms are superseded by severe præcordial pain, weak and rapid pulse, sighing respiration, borborygmus and belching of wind, muscular rigidity, and later paralysis of the whole body except the brain, which is unnaturally active. In such a case he used a large teacupful of clear coffee, and has found it equally efficacious on subsequent occasions. It can be administered cold or hot. He makes no mention of amylnitrite.

Gluck (Ibid.) advocates dissolving the cocaine in a 3 per cent. solution of phenol. This, he claims, prevents the toxic effects of the former drug and renders the solution stable; as is well known, such solutions otherwise lose their anæsthetic effect after twenty-four hours. Phenol, besides, has a certain anæsthetic power of its own, forms a superficial eschar, which prevents absorption of the cocaine, destroys bacteria, fungi, etc., prevents decomposition in the solution, renders it aseptic and wards off reactive congestion.

The Use of Cod Liver Oil in Rheumatism.

Cod liver oil has obtained such a definite reputation against tuberculous and scrofulous affections that we are apt to forget its virtues in other maladies. In the first instance, it was employed against chronic rheumatism, and gained enthusiastic opinions. I have before me the original report in reference to this latter use by Dr. Bardsley, of Manchester, who in April, 1807, wrote that it had then for thirty years enjoyed a very high local reputation. It had been much used in the Manchester Infirmary by Dr. Percival and by Dr. Bardsley himself. The latter reports that it is variable in its efficacy, often in the mild and more common forms not doing any appreciable good. He thought it most useful in chronic cases in elderly persons and in women debilitated by parturition. He thought that it seldom did good unless it fattened. His dose was half an ounce to an ounce and a-half twice a day, and he found warm beer to be, with the laboring classes, the favorite vehicle. If benefit was obtained, it ought to be continued for six or eight months. He asserts:

"I have seen a few patients recover entirely by the exhibition of the oil who on their admission into the house were unable either to preserve the body in an erect position, or support its weight on the lower extremities." The consumption of cod liver oil in the Manchester Infirmary from 1776 to 1807 had averaged fifty or sixty gallons annually. It now amounts to four hundred gallons. The profusion with which new chemical remedies have been supplied to us of late years may, it is very possible, have led to the comparative neglect of old ones, and that, perhaps, not always to the advantage of our patients.—Arc. of Surg.

MEDICINE

The Disadvantages of Hot-water Bottles

The custom which so largely prevails mainly among ladies of using hot-water bottles in bed for the purpose of warming their feet, time-honored as it is, cannot after all be said to have had much to commend it. Indeed, there is a good deal more which can be urged against it than can be said in its favor. Ladies who resort to the habit, for habit it soon becomes in the majority of instances, suffer from cold feet, a condition which, it is needless to say, does not particularly conduce to the wooing of sleep. But cold feet is a symptom which should not be left to be dealt with at the end of the day; on the contrary, those in whom it occurs should bear in mind that in ordinary health the proper remedy for this condition is exercise. Nothing tends more to cause "cold feet" than sitting about the house all day, or reducing the daily exercise to a minimum amount, either on account of laziness or feebleness of will-power for exertion. Some persons console themselves with the reflection that they were born with cold feet, and on these grounds hold that it was always intended that they should warm them by artificial means, thus ignoring the necessity which exists for exercise. Hot bottles, too, used in this way become a fertile source of chilblains, and, moreover, are not devoid of danger. We heard the other day of two cases in which the ladies using them were seriously scalded by the cork of the earthenware bottle containing the boiling water suddenly popping out. This brings us to the consideration of whether hot bottles should be used at all, and we think the answer should be in the negative. The best way of warming cold feet at night is to clothe them with warm woolen socks or stockings, which may be slept in. By this means the temperature of the feet is gradually raised, and is equably maintained throughout the night without trouble or risk. Another useful plan is to raise the feet on a pillow about two inches above the knee, so as to facilitate the return of the blood through the veins of the limbs.—Med. Press.

The Knee-jerks in Supervenosity.

Hughlings Jackson has observed that knee-jerks are absent in some cases of emphysema with bronchitis, where the blood has become venous to an extreme degree. Dr. Russell, at his suggestion, examined the knee-jerks of a dog, artificially asphyxiated by clamping its trachea; the animal's knee-jerks became exaggerated until knee clonus was produced; but in the third stage of asphyxia, no reaction could be obtained. As asphyxia diminishes, and in an extreme degree annuls, the excitability of the motor cortex, it may be that the preliminary exaggeration of the knee-jerk observed by Dr. Russell, was owing to loss of cerebral control upon lumbar centres, and that these spinal centres succumbed later to the influence of supervenous blood, than did the controlling cerebral motor centres. When oxygen is given to cyanosed patients, their

knee-jerks should be tested before and after the gas is administered. If successfully used, that is, if the patient's blood becomes well oxygenated, it is possible that knee-jerks obtainable before administration of the gas, may be elicited afterwards. If supervenosity causes loss of the knee-jerk, the fact may be important with reference to the apoplectic state, and also with regard to post-epileptic coma. In some cases of apoplexy from cerebral hemorrhage, the knee-jerks are lost, in others not. The author suggests investigating these points in all cases of supervenosity. —Brit. Med. Jour.

The Etiology of Acute Bright's Disease.

Agnes Bluhm (Deutsch. Archiv. f. klin. Med.) has classified the causes of all cases of Bright's disease occuring in the Medical clinic at Zurich, during a period of 5½ years. The infectious diseases are the chief cause of acute Bright's disease, occuring as it does after typhoid fever, acute exanthemata, erysipelas, variola, diphtheria, tonsillar angina, croupous pneumonia, acute peritonitis, and acute miliary tuberculosis. Among the chronic infectious diseases, tuberculosis and syphilis are mentioned; a number of skin diseases are also included. Eczema, psoriasis, tuberculosis cutis, and erythema nodosum. Among toxic causes, three cases are noted following the use of mercury, lead and thallin. Among the other causes of acute nephritis are mentioned; intestinal diseases, icterus, circulatory affections, pregnancy, leukemia, and gonorrhea. In nine per cent. of the cases, no etiology could be determined. The causes of the chronic parenchymatous form of nephritis are more uncertain, but it was due in the larger number of cases to malaria, misuse of alcohol, and unhygenic conditions. Among the causes of genuine contracted kidney, syphilis was present in eleven per cent. and arteriosclerosis in 17.7 per cent. of the cases; misuse of alcohol and lead were also concerned in the etiology of this form of nephritis. Regarding the development of acute nephritis after acute infectious diseases, it was observed that neither the severity nor the course of the primary affection exerted any special influence on the nephritis.—Cent. f. klin. Med.

SURGERY.

Poultices are remedial when the "sign is right," but some physicians have trouble in discerning when it is right, and place the poultice on the wrong place. A poultice should not be applied to a recent wound unless the physician wishes to interfere with the "vis medicatrix naturæ." It seems almost incredible that a physician will advise that a crushed finger, hand or other injured part be poulticed, and advise this measure day after day; but such is the lamentable fact. We call attention to this poulticing of recent wounds in particular, because it has been our luck to see several cases of this form of malpractice recently, and if any one who is in the habit of poulticing recent wounds should happen to see this we will be amply repaid if he or she will stop and consider the harm that will be done by so unscientific a procedure. If you wish heat and moisture for the relief of pain and congestion, immerse the part in hot water until the effect is accomplished. This will give greater satisfaction to your patient and do real good. "The sign is right" for a poultice when you wish to devitalize the part and hasten or promote the suppurative process. Don't apply them to recent wounds. —Kansas Med. Jour.

Treatment of Hemorrhoids.

Mr. J. Brindley James states (Brit. Med. Jour.) that for some years he has been in the habit of treating hemorrhoids by the simple process of applying calomel to them with the finger alone, and without a single exception he has done so with marked success, especially when inflammatory action was obvious in the hemorrhoidal mass, characterized by mucous discharge, and hemorrhage, accompanied by a most painful sensation of weight in the rectal region. All these symptoms under this simple influence were speedily relieved, with the still more important subsequent advantage of the patient's restoration to ease. A short time since a patient came to him suffering so acutely that he could neither sit nor walk freely, each movement of the body entailing excruciating pain. He has now seen him thoroughly enabled to pursue his usual occupation in happy immunity from these distressing symptoms.—Ex.

Treatment of Appendicitis.

Appendicitis of the perforating type may generally be diagnosed by symptoms of shock, which speedily appear after the ulcerated appendix has developed. An anxious countenance; blue finger-tips; nose and ears cold; pulse and respiration excited, rapid or sighing, and out of relation with the temperature; tenderness in the abdomen; pain in the abdomen, generally in the neighborhood of the right inguinal region, are pretty reliable data for diagnosis of perforating appendicitis. When these symptoms occur in a case, there is no alternative but to open the peritoneal cavity and remove the offending appendix. But in another type of appendicitis, in which there are none of the symptoms of shock above described, except tenderness in the inguinal region with more or less rise of temperature, a surgeon may wait until he is satisfied that suppuration exists, and then incision should be made and the abscess evacuated. If the appendix can be readily reached and separated from the surrounding structure without breaking through the neighboring adhesions of the peritoneal cavity, it may be removed; but in the majority of cases of suppurating peritonitis in which there is a local abscess about the appendix, which can be reached without perforating the peritoneum, it is better to simply drain the cavity than to insist upon a removal of the ulcerated appendix.—Col. and Clin. Rec.

Can a Septic Bullet Infect a Gunshot Wound.

L. Lagarde (New York Medical Journal) says:

The vast majority of cartridges in original packages are sterile and free from septic germs. This is due to the thorough disinfection and absolute cleanliness observed in the process of manufacture.

The disinfection with heat, acids, and alkalies, and the rigid rule of cleanliness used in the process of manufacture, are employed to exclude grease and dirt, as the latter impair the keeping qualities of the powder and disturb ballistic values.

The majority of gunshot wounds are aseptic, because the vast majority of the projectiles inflicting them are either sterile or free from aseptic germs.

Cartridges out of original packages show micro-organisms upon them, and these are not entirely, if at all, destroyed by the act of firing.

Anthrax, when applied to the projectile of a portable weapon, is seldom if ever entirely destroyed by the act of firing.

When a gunshot wound is inflicted upon a susceptible animal by a projectile infected with anthrax, the animal becomes infected with anthrax and in the vast majority of instances dies from said infection.

The heat developed by the act of firing is not sufficient to destroy all the organic matter on a projectile, the cherished notion of three centuries and more to the contrary notwithstanding.

The results justify the assumption that a septic bullet can infect a gunshot wound.

OBSTETRICS.

Prevention and Cure of Puerperal Sepsis.

In a paper on this subject (Cin. Med. Jour.) Dr. W. W. Potter arrives at the following conclusions:

1. Obstetric engagements once accepted should be faithfully fulfilled, no matter how awkwardly they fit. Apply the same rule of cleanliness to the poor and rich alike. Decline service when this cannot be done. Human life is too precious to jeopardize it by slip-shod, half-hearted or indifferent service.

2. The physician should be a model of cleanliness in body and clothing, and should insist upon the observance of similar conditions by all persons in and about the lying-in chamber.

3. The delivery room, whether in hovel or palace, court, alley, or avenue, should be simple in its furniture and hangings, and be cleaned with soap, water, and whitewash (if possible to use the latter) immediately before occupancy by the puerpera.

4. The delivery bed should consist of a new tick filled with sweet and clean straw, covered with a blanket, impervious dressing, and a folded sheet, with other covering to be allowed according to season. Exceptions to this simple bed should be as few as possible, and in no event should a bed be substituted that has been used by the sick, or that is not beyond even a suspicion of infection.

5. The patient should be especially prepared for delivery by baths and enemata, vaginal douches, and clean clothing; and labor should be conducted on the lines of absolute cleanliness, with few digital examinations and a complete delivery of the secundines.

6. Lesions of the genital tract should receive careful attention; rents of the perineum should be repaired, and so, too, in some instances, should tears of the cervix.

7. Antiseptic solutions containing a germicide should be used for cleaning the hands and instruments of the operator. Intrauterine irrigation with sterilized water should be carefully employed after operative midwifery, either manual or instrumental.

8. Finally, if sepsis proceeds to suppuration and abscess the abdomen should be opened, pus cavities emptied, irrigation used, and drainage established. If the uterus and adnexa become thoroughly infected they should be extirpated.

NEWS AND MISCELLANY.

The Medical Society of the State of Pennsylvania will meet in Williamsport, May 16, 17, 18 and 19. All who desire to read papers at the session must submit them by title and probable time needed, to Dr. H. G. McCormick, Chairman of the Committee of Arrangements, Williamsport, not later than March 1st.

ARMY AND NAVY.

FROM JANUARY 1, 1893, TO JANUARY 7, 1893.

First Lieutenant Isaac P. Ware, Assistant Surgeon, U. S. Army, is assigned to duty at Fort Sill, Oklahoma Territory until further orders.

The leave of absence for two weeks, on surgeon's certificate of disability, granted to Captain Adrian S. Polhemus, Assistant Surgeon, U. S. Army, is hereby extended fourteen (14) days, from December 30, 1892, on surgeon's certificate of disability.

Lieut. Col. Charles H. Alden, Deputy Surgeon General, U. S. A. to be Asst. Surg. Genl. with the rank of Colonel, Dec. 4, 1892, vice Heger, retired.

Major Albert Hartsuff, Surgeon, to be Deputy Surg. Genl. with rank of Lieut. Col. Dec. 4, 1892, vice Alden, promoted.

Capt. Louis M. Maus, Ass't. Surgeon, to be Surgeon, with the rank of Major, Dec. 4, 1892, vice Hartsuff promoted.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.
(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Sodc, one or two pills taken three times a day.

Pil. Lady Webster.
(WM. R. WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.
(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.
(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

The Demand For

a pleasant and effective liquid laxative has long existed—a laxative that would be entirely safe for physicians to prescribe for patients of all ages—even the very young, the very old, the pregnant woman and the invalid—such a laxative as the physician could sanction for family use because its constituents were known to the profession and the remedy itself had been proven to be prompt and reliable in its action, as well as pleasant to administer and never followed by the slightest debilitation. After a careful study of the means to be employed to produce such

A Perfect Laxative

the California Fig Syrup Company manufactured, from the juice of True Alexandria Senna and an excellent combination of carminative aromatics with pure white sugar, the laxative which is now so well and favorably known under the trade name of "Syrup of Figs." With the exceptional facilities, resulting from long experience and entire devotion to the one purpose of making our product unequalled, this demand for the perfect laxative

is met by Our Method

of extracting the laxative properties of Senna without retaining the griping principle found in all other preparations or combinations of this drug. This method is known only to us, and all efforts to produce cheap imitations or substitutes may result in injury to a physician's reputation, and will give dissatisfaction to the patient; hence, we trust that when physicians recommend or prescribe "Syrup of Figs" (Syr. Fici Cal.) they will not permit any substitution. The name "Syrup of Figs" was given to this laxative, not because in the process

# of Manufacturing

a few figs are used, but to distinguish it from all other laxatives, and the United States Courts have decided that we have the exclusive right to apply this name to a laxative medicine. The dose of

"SYRUP OF FIGS"

as a laxative is one or two teaspoonfuls given preferably before breakfast or at bed time. From one-half to one tablespoonful acts as a purgative, and may be repeated in six hours if necessary.

"Syrup of Figs" is never sold in bulk. It is put up in two sizes to retail at fifty cents and $1.00 per bottle, and the name "Syrup of Figs" as well as the name of the California Fig Syrup Company is printed on the wrappers and labels of every bottle.

FIVE CASES OF VAGINAL HYSTERECTOMY FOR MALIGNANT DISEASE OF THE UTERUS.—ALL RECOVERED.*

W. F. McNUTT, M. D., M. R. C. S., Ed., etc., San Francisco.

Case I. Mrs. B., age 57, born in New York, had one child, 1851, no cancer history, menstruated at 17, ceased at 41. At age 53 commenced having slight uterine hemorrhages; consulted several physicians in regard to it, had taken medicine and had astringent injections, etc., with the effect of partially controlling the bleeding. When she consulted me first at my office she had slight hemorrhage, mixed with a thick, ropy albuminous looking discharge—found the uterus slightly enlarged, canal tortuous and irregular, and had difficulty in passing the sound; neck granular and bleeding easily; made applications with astringents, ordered lead and carbolic injections, advised rest. There being no improvement and considering the case cancerous, I called Dr. Beverly Cole in consultation, when we dilated the uterus with Hager dilators. There was discharge of at least half an ounce of white-of-egg-like fluid mixed with blood, the whole neck of the uterus was nodular and presented an epithelial-like softened appearance. The woman was losing weight, strength and color; there was no mistaking the diagnosis, viz., *epithelial cancer.*

Mrs. B., having consented to an operation, I determined to make a vaginal hysterectomy, and on November 27th, 1888, removed the uterus. The external parts were shaved and thoroughly cleaned by soap and carbolized water, the vagina was disinfected and the patient placed in the dorsal position. The uterus was brought down by a strong vulsella and a small vertical incision was made through the anterior vaginal wall. An aneurism needle with a ligature was passed through the opening, and brought out through the wall three-fourths of an inch to the right; this section was tied and divided with scissors; this process was continued until the neck was enucleated; the connective cellular tissue was mostly broken up by the finger; the uterus was then easily brought further down, not turned over, and the broad ligaments secured *en masse* by a carbolized silk ligature. I then put long compression forceps on the ligaments between the ligature and uterus, and divided the broad ligaments close to the uterus up to its upper margin, and over this undivided upper fold of the ligament I placed a ligature and cut the uterus free. I then tied these last two ligatures together stretching the broad ligaments across the cavity and making a roof, as it were, to the vagina; the vagina was then packed with iodoform gauze; the forceps were taken off in forty-eight hours. She was kept four weeks in bed; and seventeen months after the operation she was as well as she ever was. At no time after the operation was there any marked rise in temperature.

Of the pathology of this case Prof. D. W. Montgomery says: "Mrs. B. had an extensive neoplasm of the cervix uteri, both simple and malignant. The simple new growth was a papilloma. Below the papilloma was a epithelioma infiltrating very extensively the connective tissue."

*Read before the California Medical Society.

Case II. Mrs. P., aged 44, married at 20, two children, youngest 17 years old, had one miscarriage 13 years ago, no cancer history. This case was under the care of Dr. W. H. Davies, who had attended her for several months for uterine hemorrhage, using internal remedies, injections and several times having to tampon the vagina with cotton saturated with Monsel's solution.

Dr. Davies told her his efforts were only affording her temporary relief and more radical measures would have to be tried. I was called in consultation and found the patient exsanguine to an alarming degree; an epithelioma of the cervix was unmistakable; the slightest touch caused profuse bleeding, necessitating the tampon after our examination. We advised removal of the uterus, and after a few days' delay she consented to the operation. July 25th, 1889, the operation was made. I gave the patient ether, and, placing her in the lithotomy position, the epithelial fungoid bleeding mass was curetted off and the bleeding in a measure controlled by hot water before enucleation of the cervix was commenced. Drawing the uterus well down with a vulsella the enucleation was soon made, the adhesions separated, and the broad ligaments clamped with compression forceps (no ligatures used), uterus cut loose. The forceps were left on fifty hours. The only difficulty encountered in this operation was the exhausted and exsanguined condition of the patient before commencing the operation. During the latter part of the operation she was constantly plied with hypodermic injections of whiskey, which were necessary to keep up the heart's action.

The patient was in excellent health and spirits nine months after the operation, with the exception that she has a small vesico-vaginal fistula, which did not give any evidence of its presence until after the fourth week.

Case III. *Hysterectomy (for cancer) and Ovariotomy—Double Operation.* Mrs. F., age 67, a thin, wiry, but apparently well nourished old lady came to Dr. R. M. Elliott, of this city, from Washington Territory, on June 24th, 1889, suffering from an offensive discharge from the uterus. She had borne a large family of healthy children, and never had any severe illness up to the present time.

While riding on a buckboard about five months ago, the horses in leaping a ditch tipped her backwards, and she fell, striking on her sacrum. The injury caused her considerable pain at the time, but it gradually passed off leaving no noticeable trouble afterwards. A smooth, elastic, immovable, round tumor could be felt through the abdominal wall in the region of the ovary. There was a purulent vaginitis and an excoriation of the os uteri with a purulent bad smelling discharge from the os. There had been at no time either pain or hemorrhage. After cauterization by Dr. Elliott with nitrate of silver, (the solid stick), the excoriation healed in part, the discharge from the os in a great measure ceased, and she returned to the country much improved, but with a slight discharge from the vagina which still persisted, and for which an injection of sulphate of zinc and acetate of lead, each 20 grains, tincture of opium one drachm, and water to eight ounces, was prescribed.

After two weeks she wrote stating the offensive discharge had returned just as before. On coming back to the city again for treatment a much more serious state of affairs was found than at first. The discharge was as abundant as before instituting treatment, and a fungoid, easily bleeding mass was seen projecting from the os uteri.

Dr. Elliott called me in consultation and an operation was advised, the patient was sent to the Children's Hospital and the date of operation set for August 11th, 1889.

Because of the abdominal tumor, the exact nature of which could not be determined before the operation, it was decied to first open the abdomen, examine its contents, and then act *pro re nata*. After a careful toilet, the abdomen was opened in the median line, and an ovarian cyst about the size of a cocoanut was found united by extensive adhesions to all the surrounding viscera, especially to the intestines. The adhesions were carefully separated, principally by the finger nails. After much labor the tumor was set free from the intestines, it still being firmly adherent to the uterus. The cyst contents were then evacuated. The uterus was found much enlarged; being about the size it should be at the second month of gestation; it was soft and boggy to the touch; adherent to the

surrounding tissues, especially posteriorly, an abscess being found between the uterus and the rectum. I then decided to enucleate the neck of the uterus per vaginam and remove the uterus through the abdominal opening. In enucleating the neck and going up between the rectum and the uterus the aforementioned abscess was opened and a large quantity of foul smelling pus was evacuated. The os uteri was also opened up and a large quantity of pus came away from the uterine cavity. The pus being got rid of per vaginam, and the neck being thoroughly enucleated, the operative procedures were subsequently carried on through the abdominal opening, removing the entire womb, the cyst in connection with it, and the left Fallopian tube.

Despite the age of the patient, the length of the operation (lasting fully three hours) and the amount of disturbance caused by the breaking up of the very extensive adhesions and the separation of such large masses of tissue, the patient's temperature never went above 101°, and the only bad symptom was some meteorism occurring on the third day and gradually subsiding again. Very little blood was lost during the operation; a point of great importance in elderly persons in whom the blood-making functions are not active.

Dr. D. W. Montgomery's report on the pathology of the parts removed, appeared in the reports of the San Francisco Medical Society where the specimens were shown. He says that it was an epithelioma of the cervix uteri, the infiltrations involving pretty much the whole cervix.

Case IV. Mrs. P., aged 32, married, had children, was under Dr. S. S. Stambaugh's care for several months for fever, pain and uterine hemorrhage. I examined her in consultation with Dr. Stambaugh August 27, 1889; the uterus was much enlarged and immovable, cervix nodulated and vascular with granulating bleeding surface; broad ligaments thickened. There was a bad smelling vaginal discharge. There was no doubt about the cancerous nature of the disease. Mrs. P., came from a very malarious locality, and had high fever every day, notwithstanding Dr. Stambaugh had treated her for malaria.

We informed Mrs. P. of the nature of her disease, and that nothing but an operation offered her any chance from a disease which must soon prove fatal. The enlargement and fixed condition of the uterus with the involvement of the broad ligaments made the prospect for an operation bad. She, however, wanted to avail herself of the chance an operation would afford, and on September 12, 1889, I operated. After careful preparations as to washing, shaving and vaginal antiseptics, the uterus was seized with a strong vulsella, but on account of the fixed condition could be pulled down but little, the neck was soon enucleated with instruments which I had made for the purpose.

The extensive adhesions were broken up with great difficulty, and the ligaments were so involved that it was necessary to remove them.

The hemorrhage was controlled by compression forceps, which remained on about fifty-two hours; no ligatures used; the vagina filled, as in all the other cases with iodoform gauze, and the woman put to bed. She at no time had so much fever after the operation as she had before, and she made a good recovery.

Case V. Mrs. W., aged 38, born in France, first menstruated at the age of fifteen, never was regular; married at twenty-three, one miscarriage five years after caused by lifting a heavy weight, followed by metritis and peritonitis, was confined to bed two months, never fully recovered; no cancer history.

Began to complain of uterine pain and hemorrhage about three months ago, for which she had consulted physicians at various times, who had given her medicine and injections without relief. She consulted Dr. Frances R. Marx, who, considering the case cancerous, called me in consultation. On examination I found great tenderness; the whole uterus enlarged and fixed; cervix indurated and nodular, with very vascular granulations which bled freely from the slighest touch; there was a constant watery, bloody colored discharge, having a characteristic odor; the cancerous cachexia was well marked and the diagnosis of cancer was unmistakable.

Being informed of the nature of her case and the only remedy, removal of the uterus, she at once consented to an operation. She was sent to the Children's Hospital. December 3, 1889, I removed the uterus. On account of the large size and fixed condition of the organ, accompanied by the fact that the woman had never

borne children, the operation was a most difficult one. After enucleating the cervix and separating the adhesions to the bladder it was still impossible to pull the uterus down—the attempt to turn it over backward was equally unsuccessful. After a time, however, I succeeded in turning it over forward, having fixed one blade of the vulsella into the fundus and made steady traction. The broad ligaments were then clamped with compression forceps (no ligatures used), and the operation finished by cutting the broad ligaments. The vagina was packed with iodoform gauze and the forceps removed after forty-eight hours. This large fibrous tumor which you see in the fundus of the uterus is what prevented the uterus from descending and made it so impossible to turn it over backwards.

The operation altogether was very difficult, and the hemorrhage from this softened, vascular, broken down, cervical portion was excessive and uncontrollable during the operation. The woman, though exsanguine by the time the operation was finished, made a good recovery, and is at present enjoying very fair health.

The first operation was the only one in which I used the aneurismal needle and ligature in enucleating the cervix. In the other cases the enucleation was done with instruments which I made for the purpose.

My object in reporting these cases is to call attention to the fact that we have in hysterectomy a remedy even for cancer of the uterus; to assist in establishing hysterectomy as a legitimate and recognized surgical operation, and to hasten the time when the surgeon will as promptly and confidently resort to removal of the uterus for cancer as he does to the removal of the breast.

Of these five cases all were married women, four had borne children, while the fifth case had had one miscarriage.

About the frequency of cancer of the body of the uterus, as compared with that of the cervix, there is great diversity of opinion, as is also the case in regard to the merits of the operative procedure for cancer of the cervix—whether to remove the cervix only or to make hysterectomy.

A recent able writer on cancer of the uterus, Dr. John Williams, Professor of Obstetrics in Queen's College, London, strongly advocates amputation of the cervix when the cancer apparently involves only the cervix, saying: "That it is possible to extirpate cancer from the uterus by supra-vaginal amputation, and that, in so far as the prevention of recurrence in the uterus is concerned, total extirpation of the organ presents no advantages over partial amputation."

It is not so surprising that Dr. Williams takes this ground, as he believes he has fully demonstrated that the tendency of cancer of the cervix is to spread laterally rather than to follow up the uterine cavity and involve the body of the womb. A careful examination by Professor Montgomery of the uteri of my cases does not go to confirm Dr. Williams' opinion, that in cancer of the cervix the tendency is only to extend laterally. Dr. Montgomery found the cancer cell extending up the mucous lining of the uterine canal.

While Dr. Williams advocates and practices the supra-vaginal amputation, he certainly has failed to make it clear how we are to diagnose with any certainty in which cases there is no cancerous involvement extending above the cervix.

There may be cases when this supra-vaginal amputation would be all that is necessary; in many cases, however, the cancerous tissue would not all be removed, and there is no means of differentiating the cases.

In connection with these cases, I will crave the indulgence for a word about laparotomy. Now, that laparotomy has become so common, no one thinks of making an elaborate and detailed account of this operation. In the past year I have, however, made three or four that are not devoid of interest to those who are interested in abdominal surgery.

Two of the cases appeared to be intra-ligamentous cysts. One very large, with no pedicle, was imbedded between the layers of the broad ligament deep in the pelvis. Enucleation was first attempted, but the capsule was so vascular that the attempt to shell it out had to be abandoned. I finally tied its whole broad base in eight sections. Including too much tissue in the last section next to the uterus, the ligature cut the tissues and the bleeding was profuse. After cutting away the sac close to the ligatures, I resorted to powdered Monsel's to stop the hemorrhage, which it did, using about three teaspoonfuls. A drainage tube was used, and the wound closed in the usual manner. There was

considerable inflammation, with a temperature of 104° for three or four days, when the fever subsided and the patient made a good recovery. She was out in five weeks. In the second intraligamentous case the cyst was small and there was no difficulty in enucleating it. The hemorrhage, however, was very profuse, and was again checked by putting Monsel's freely into the bed of the cyst. A drainage tube was used. Some fever followed, and the woman made a good recovery. These two cases made up my experience with Monsel's in the abdominal cavity. Just how to manage these intraligamentous cysts seems to be a matter for each individual operator to determine after he has opened the abdomen and carefully examined the case at hand.

The third interesting case was that of a solid ovarian tumor weighing between seven and eight pounds. The woman, though very weak, made a good recovery. Professor Montgomery, after a careful examination, determined it to be fibroid. While solid ovarian tumors are not common, the fibroid variety is probably the least common of all. The most troublesome part of the operation for these solid tumors often is the management of the intestines, owing to the great length of the opening required to lift out the tumor.

CLINICAL LECTURES.

TALIPES FRACTURE OF ACROMIAL END OF CLAVICLE, DOUBLE FRACTURE OF SHAFT OF FEMUR, HARE-LIP.*

Prof. ROSWELL PARK.

This patient is a boy four or five years old who presents a well-marked case of talipes equino-varus. His parents have been too poor to provide proper mechanical support for the foot and the boy has worn a very cheap, inefficient shoe which has been of no use in correcting the deformity. They consulted me with reference to an improved form of shoe but I told them that I should not recommend a shoe until after an operation.

The question arises, is this a case in which the deformity is due to essential muscular weakness, or has the apparent atrophy of the muscles come about from lack of use of the foot? The peronei tendons on the outside of the foot and leg act like a bridle rein opposed to the tibiales tendons on the inner side. Naturally, if the peronei are paralyzed, the foot will be turned in and I think the present condition is largely due to such trouble. Even if the weakness of the peronei were not the original cause, the deformity is at least perpetuated by their present inability to overcome the pull of the tibiales.

After cleansing the foot and leg and applying an Esmarch bandage, I will cut the tendo Achilles by the ordinary subcutaneous method. You will ask why the Esmarch bandage was used. Certainly not for the almost bloodless section of the tendo Achillis, but because I intend to divide the tendons on the inner border of the foot by an open incision according to the operation of Dr. A. M. Phelps, of New York. After doing this, you see that the slightest touch restores the foot to its normal position, the wound is closed by dusting iodoform over it and applying layers of iodoform gauze, bichloride gauze and cotton, and the whole is kept in place by a roller bandage. When the tourniquet is taken off, the blood will rush back into the foot and an aseptic blood-clot will be thrown out to heal the wound, which I have made.

This case being one due almost entirely to lack of muscular control of the foot, the bony deformity is not great and an operation on the tarsus is unnecessary. The foot is restored manually to its proper position and is held in a position of overcorrection while I apply a plaster-of-Paris dressing. We have every reason to expect primary union under this dressing, by the organization of the blood-clot. The parents of the child must have directions about later using massage of the leg muscles to the best of their ability. Without some such means to stimulate the peronei and the sural muscles, the foot would relapse almost to its former state and con-

* Buffalo General Hospital Surgical Clinic, reported by A. L. Benedict, A. M., M. D.

siderable care must be taken to keep the foot in its restored position by making the external and posterior muscles do their proper work.

This patient has sustained a fracture near the shoulder joint, the result of a fall on the shoulder. The doctor who first attended him diagnosed fracture of the acromion and applied a dressing which was not disturbed till I saw the case two days afterward. It struck me at the time that the dressing could not keep acromion in place as there was no provision for pushing the arm upward against this prominent process. On removing the dressings to see how much the acromion had dropped from its proper position, I found that it had not dropped at all, showing that it could not have been fractured. On manipulation, I got obscure crepitus which I succeeded in localizing at a point within half an inch or so from the junction of the clavicle and the acromion so that we must modify the diagnosis and say that the case is one of fracture of the acromial end of the clavicle. You will ask what is the necessity of making such an accurate diagnosis. Because a corresponding accuracy of treatment is necessary. You must know what part is injured in order to know in what position to place the shoulder. If the clavicle is fractured, you must push the shoulder upward, outward and backward. If the acromion is fractured you must rather raise the arm in order to push up the broken piece.

On inspecting the shoulder, you notice very little deformity. Apparently, the fracture is so near the joint that the outer end of the clavicle is held by the coracoclavicular ligament and thus there cannot be much displacement. All that is necessary, then, is to hold the parts quiet by a simple retentive dressing. We have met this indication by part of the Sayre adhesive dressing passed around the arm and body, and, over this, a roller bandage has been applied and the hand is kept in a sling. I show you this case, not to call attention to any error on the part of another, for the original dressings were sufficient to keep the parts in place, but to emphasize the importance of making an exact diagnosis and to show you a comparatively rare and fortunate location of a fracture.

I also wish to call your attention to an interesting phenomenon and one which has here, something of a diagnostic value. Over the anterior and upper part of the chest you see an ecchymosis, not fresh as it would be from a recent superficial contusion, but showing the faded colors of an old extravasation of blood in which chemical changes have occurred. This is a common appearance after fracture of any bone, the blood working its way to the surface after several hours or after two or three days, according to the distance of the bone from the skin. Now, if the fracture had been one of the acromion process, the ecchymosis would be seen over the peak of the shoulder and posteriorly on account of gravitation while the patient is lying on the back. The blood could scarcely penetrate the deltoid muscle, so that the discoloration of the anterior part of the chest and the absence of such discoloration from the back and top of the shoulder are contradictory to the diagnosis of fracture of the acromion. Ecchymosis is practically of little value in the immediate diagnosis of fractures since it can not be seen till after the injury should have been located and the dressing applied.

This patient is a victim of the boom at Niagara Falls, having been injured while at work in the tunnel by a large stone falling on his thigh. The femur was broken in two places, just above the knee and ten or twelve centimeters higher. It is now six weeks after the accident and the case is brought before you as an illustration of the results of treatment. The patient is a young man of twenty-four, previously healthy and we should expect that the necessity for confinement and rest in bed has passed away. I wish, however, to manipulate the limb to determine the degree of consolidation and to make sure that it is sufficient to warrant leaving off the dressing. As I grasp the bone through the soft tissues, it seems fully twice as thick as on the opposite side, this increase in size being due to the callus which was thrown out after the double injury and which has been more or less organized into bone. In course of time, most if not all of this enlargement will probably be absorbed. As I rotate the leg at the knee, the trochanter moves in correspondence as it should if the femur is again one piece. Grasping the femur with both hands, I am

unable to make any motion in the middle, either by rotating it or by trying to bend the bone.

I also wish to measure the leg to note the shortening, a moderate degree of which is to be expected after any fracture of the femur and especially after a double fracture. We must be careful to get the legs perfectly parallel, having the pubes, umbilicus and internal malleoli in the same line. Measuring from the anterior superior spine of the ilium to the internal malleolus of the sound side first, I find the distance to be 33¼ inches. I make it a rule never to look at the tape-line until after I have determined by the sense of touch the exact points between which to stretch the line. In this way I avoid any possible self-deception. I find the measurement of the injured side to be thirty-three inches. By the dictum of the American Medical Association, a shortening of three-quarters of an inch is not a bad result and is quite consistent with the most skillful treatment. With a double fracture, it would not be at all surprising if an inch or an inch and a quarter of shortening had occurred. We must congratulate ourselves on having secured a minimum of it here. This has been obtained only by traction with a relatively very heavy weight, at first, of twenty pounds. Although consolidation has taken place, it would not be wise to allow the patient to get up and exert pressure on the bone, since some further shortening is still possible, but he can be relieved of the irksomeness of the bandage. His leg will be rested on a pillow and passive motion will be used so as to allow the knee to recover its mobility.

This case is a simple form of hare-lip occurring in a child aged sixteen months. The explanation of the trouble is easy if we understand a little about embryology. The two halves of the face are developed separately and grow toward each other. A cleft in the lip, like a cleft in the palate, indicates a failure of complete fusion of originally separate parts. In certain animals, the hare especially, such a failure is, so to speak, intentional. In the human being it constitutes an abnormality and, on account of the disfigurement, it is one which the surgeon is often called upon to remedy. The failure to fuse may be present in any degree from a slight notch in the lip to a fissue extending up the side of the nose and backward through the palate to the pharynx. Such extreme cases of combined fissure of the face and palate are almost beyond the full restorative power of surgery. Hare-lip, as well as cleft palate, is almost never found exactly in the median line. Many mothers try to explain its occurrence by recounting some fright which they had late in pregnancy. The deformity, however, dates back to the fifth or sixth week of fœtal life so that, without reference to the general possibility of maternal impressions affecting the child, such an explanation can not hold good in most cases of hare-lip and cleft palate.

The operation for the relief of hare-lip is in theory a simple one. It consists in freshening the edges of the cleft and sewing them together. In practice, however, this may be a very difficult plastic operation. I usually tell the parents that, although I can bring together the edges in any case of hare-lip, I can not ensure the union of the wound for the simple reason that the child in fretting and crying, may tear the stitches loose. We try to avoid this accident by reinforcing our stitches. Sometimes hare-lip pins are used to transfix the parts and a silk ligature is wound in figure-of-eight fashion over the ends of the pins. Sometimes sutures are passed through the cheeks and held by lead discs. Often the wound is dressed with iodoform and protected with collodion, and some rely on the stiffening of the collodion to prevent the child from moving the lip in crying. But the discharge from the nostrils or the saliva or food may loosen the collodion so that this dressing often fails.

Several operations have been devised to relieve different forms of hare-lip, all following the same general principle but differing in detail. For instance, we may cut parallel to one edge of the cleft, nearly to the margin of the lip and then turn inward so as to leave a tag of tissue at the lower part of the cleft. On the other side we do no remove as much tissue but we make a similar angle to aid in coöplating the parts.

In this case the defect is so slight, not extending to the nostril, that it is necessary only to freshen the margin of the cleft.

Our Continental friends have a way of operating on hare-lip without giving an

anæsthetic. I do not consider it any advantage to avoid the theoretical evil of giving an anæsthetic by allowing the child to suffer so much pain as the operaton necessitates.

The alveolar border is not exactly regular, but is nearly so and it requires no operative interference. The teeth are not quite regular and one is turned half way round and will require the attention of a good dentist at some future time. At present I forbear to do anything but rectify the labial fissure, lest with this rather feeble child I do too much, and perhaps totally fail. What remains to be done beyond this may be better done a little later.

COMMUNICATIONS.

CEREBRAL SYPHILIS.*

Dr. J. E. HAYS.

I have prepared this paper with the object of presenting in as condensed form as possible, the history of two cases of cerebral syphilis that have lately come under my care.

An interesting feature of each case is the wide interval of apparent cure between the disappearance of the secondary manifestations and the beginning of the cerebral disturbance. As both cases were accompanied by paralysis which was hemiplegic in character, they forcibly illustrate the danger and serious effects that may possibly result from the product of a syphilitic dyscrasia.

Case I. Mr. P., aged forty-six; an Englishman. I was called to see this case February 1st, 1892, and found him with complete paralysis of the left arm and leg; his power of speech was slightly impaired, and there was also some difficulty in swallowing. The attack had been sudden and was not attended by any loss of consciousness. Prior to the loss of power on left side, there had been no complaint of pain in the head; no vertigo; no staggering or uncertain gait; in fact, no symptom that would indicate an approaching paralysis. His general health for many years previous to the attack had been excellent; his habits had been regular; he used nothing alcoholic nor tobacco in any form; his occupation was that of foreman in a large manufacturing establishment in this city.

A careful inquiry into the previous history for something that would throw light on the cause of the hemiplegia revealed the following: At the age of twenty-six he contracted syphilis. The primary sore was cauterized and internal treatment, the nature of which he did not know, continuously administered for several months. Following the initial lesion had been some glandular enlargements, slight falling out of hair, but no eruptions on the face or body. From the history it seemed to me that there could be very little doubt in regard to the nature of the lesion that had occasioned his paralysis, and he was at once given iodide of potash in gradually increasing doses. For two months his improvement was very satisfactory; in this time he had sufficiently recovered the use of his leg to enable him to walk about; but his arm was still almost powerless. He looked, ate, and slept well. The amount of iodide of potassium had been increased to forty grains three times a day. A larger amount of the remedy was badly borne, and it was decided to continue this dose. On the sixth of April he developed a severe pleurisy on the left side; this was attributable to an exposure immediately after taking a Turkish bath. Dr. Bailey saw the case with me a few times during this attack; an effusion of moderate amount took place in the pleural sac, but disappeared under treatment in a few days. On April 20th, pleurisy occurred on the right side; this was also attended by effusion, not as great, however, in amount, as that had been on the left side. Shortly after the disappearance of this, he was seized with a violent bronchitis which so closely simulated tubercular phthisis that for a while it was calculated to deceive, especially as the attack was attended by persistent cough, profuse yellowish expectorations, rapid loss of color and strength, night sweats and a fever somewhat hectic

* Read before Medico-Chirurgical Society, Louisville, Ky., Dec. 9, 1892.

in character. His treatment at this time was mainly the syrup of hydriodic acid, a generous allowance of port wine, and plenty of liquid food. Later he was also given the compound syrup of the hypophosphites. His improvement for several weeks was very slow; the chest symptoms did not entirely disappear until September. Since then, under the use of iodides and Faradism, he has made considerable progress towards regaining the use and strength of the paralyzed limbs. A few weeks ago he resumed his work at the factory.

Case II. Mr. J., aged forty-two ; carpenter. This is a somewhat similar case to the one just reported. I saw him shortly after the attack of hemiplegia, and elicited the following facts : Eighteen years ago he had an indurated sore on the penis; secondary manifestations followed, but slight. He did not remember the duration of the treatment, but said that he continued to take medicine until the physician pronounced him cured. Since abandoning the treatment there had been no further outbreak on his skin; he married and has a son living, aged fifteen, whose upper central incisors on examination showed the characteristic malformation of inherited syphilis, as described by Hutchinson. The patient's health, notwithstanding bad hygienic surroundings and habits, had remained in good general condition until last May. At this time symptoms of vertigo made their appearance, and soon became well marked and persistent. In walking he felt an almost continual tendency to pitch forward and to the left side; his mind frequently became confused and his memory was poor. On account of the dizziness he was compelled to quit his work. The physician to whom he applied for relief, overlooking the true cause of the trouble, and thinking that the vertigo was stomachal in origin, advised him to quit the use of stimulants to which he was somewhat addicted, live on a spare diet, and keep his bowels freely moved by the daily use of a laxative water, the Carlsbad preferred. This failed to give relief. On the 2nd day of June left hemiplegia occurred; complete loss of motion but no lessening of sensation of the arm and leg. There was no loss of consciousness, slight if any impairment of his intellectual powers; he could articulate distinctly, but talked slowly and with some effort. There was no diminution in the acuteness of his vision.

The history given by the patient having established such a clear connection between syphilis and his present condition, he was at once given large doses of iodide of potassium. This was increased until he received as the maximum amount 180 grains daily. In addition to this he has at intervals also received a small or "tonic" dose of the bichloride of mercury, and Huxham's tincture of cinchona. His progress toward recovery has been rapid and uninterrupted; he has gained about twenty pounds in weight; feels well and can easily walk several squares without a cane. He has, however, regained but little use of the arm. He will probably never be able to resume his accustomed work.

The treatment of these cases presents no novelty. Clinical observation has long taught us that iodide of potassium is the sovereign remedy for bringing about an absorption of these products of syphilis. Its effect on gummata is well known and positive. While the mercurial preparations properly administered may aid, they do not approach in effectiveness the iodine compounds. Mercury, however, in the early stages of the disease has the supremacy. We very justly ascribe to it a direct and destroying effect on the virus of syphilis, whatever that virus may be. This being true, the opinion very generally prevails that it is only after a most careful, intelligent and prolonged treatment by mercury, that a physician can promise exemption from the later or so-called tertiary manifestations. In regard to a disease so grave in its possible results as syphilis, this fact ought not to be forgotten.

Black Eye.

There is nothing to compare with a tincture or a strong infusion of capsicum annuum, mixed with an equal bulk of mucilage or gum arabic, and with the addition of a few drops of glycerine. This should be painted over all the bruised surface with a camel's hair pencil, and allowed to dry on, a second or third coating being applied as soon as the first is dry. If done as soon as the injury is inflicted, the treatment will invariably prevent the blackening of the bruised tissue. The same remedy has no equal in rheumatic, sore, or stiff neck.—*Med. Times.*

SARCOMA OF THE BREAST AT THE AGE OF SIXTEEN YEARS: OVARIAN CYST.*

A. M. CARTLEDGE, M. D.

I have two specimens to present, one of which I think is of special interest. A short time ago I saw in consultation a girl sixteen years of age, with the history that six months before there was observed in the right mammary gland a tumor the size of an ordinary marble, about midway between the nipple and the axilla.

Her physician, on account of the girl's age, kept her under observation for a while, but in the last month he noticed very rapid growth of this tumor, and at the last examination, a week or ten days ago, he observed one enlarged gland in the axilla. He also observed at the last examination that the superficial veins over this tumor were very much enlarged. The girl complained of lacinating pain. As I said she was only sixteen years of age, and apparently very robust in health.

On examination a tumor of a distinctly movable character, the size of a goose egg, could be felt in the breast indicated; it seemed as if you could grasp it and it could be moved separate from the gland substance proper, and it was slightly lobulated. Below this tumor was a distinct second nodulation with a groove between the two. It seemed to correspond, as it took a more backward direction, to the lymphatic vessels going from the breast to the axillary space. At this examination I only felt one enlarged lymphatic gland in the axillary region.

As to the question of diagnosis in this case, of course it would present some features of interest. Here we had a girl whose age was decidedly against malignant tumor of the mammary gland, with a clinical history of six months duration and of pain; enlargement of the superficial blood vessels and enlargement of the lymphatics in the axillary. From the history of the case I had no hesitancy in pronouncing it sarcoma. It presented every evidence of malignant growth and the age of the patient excluded carcinoma. There was no history of trauma.

Believing that all neoplasms of the breast, without exception, should be subjected to complete extirpation and cleaning out of the axillary space, I advised this and the operation was done three days ago. The entire breast was removed, and you will observe that the tumor is distinctly encapsulated, entirely separate from the breast substance itself. The glands removed were simply the lymphatics. A thorough microscopical examination has not yet been made of the tumor.

Certainly the growth, as it appears since its removal, more than ever bears out the opinion that was conceived of it beforehand, and it has every evidence of a sarcomatous growth. The tumor presents some appearance of a fibroma superficially, but just beneath it we have this clear metastasis, with enlarged lymphatics showing its malignant character. The examination thus far has been a very rough one, the gentleman simply making a section without coloring it. He believed it would prove to be an interstitial mammitis of the breast, probably inflammatory. But the encapsulated condition indicates clearly to me that it is a sarcomatous growth, or a fibroma that has undergone sarcomatous degeneration, which we know is so common in this location. It does not present many features of an adenoma, but even this should be subjected to the same treatment.

The age of the patient is one of the most peculiar features. One gentleman, who has written on this subject, claims that the earliest age in any case of sarcoma occuring in the female mammary glands is eighteen years. However, there has been one case reported in this city at the age of fourteen. I am certain that all such growths will be considered malignant by me from a clinical standpoint.

Case 2. This specimen is of greater interest to the general practitioner than to surgeons. My attention was called to the case while visiting another patient in the same house. The lady said she had been a sufferer with dyspepsia for a long time; that she had to live principally on fluids, etc. I thought I recognized in her face the peculiar expression indicating ovarian disease. I made a careful examination and found a clear case of cyst of the ovary.

*Re d before Medico-Chirurgical Society, Louisville, Ky., Dec. 9, 1892.

Operation was performed to-day; tumor removed weighing between thirty and fifty pounds; there were no adhesions; patient bore the operation well; when she was taken off the table pulse was 80; she had no shock and nothing to indicate further trouble. This case is interesting from the fact that the woman had never complained of anything except dyspepsia and there was nothing to indicate presence of the cyst, except the enlargement which might have been due to other causes. The patient never suffered any severe pain or inconvenience from the presence of the tumor.

CLINICAL AND EXPERIMENTAL CONTRIBUTION TO THE TREATMENT WITH CREASOTE OF PULMONARY TUBERCULOSIS.*

Dr. ALBU, in Berlin.

In the Moabit Hospital in Berlin, creasote has been employed in constantly increasing doses since June, 1887, and especially latterly since the publication of Dr. Sommerbrod, in Oct. 1891, has the remedy been employed in many cases of various stages of the disease. The remedy was administered in pill form of 0.05 grammes each, and the average patient reached in the course of two weeks sixty pills per day. Many patients took 5,000 such pills in the course of a few months, and some even 9,000 pills, equal to 450 gramm (nearly a pint) of the creasote. No especial difficulty was found in the administration of these immense doses.

While Sommerbrod in the beginning recommended creasote only as a very useful remedy in the symptomatic treatment of phthisis, of late he urged it as a successful remedy against tuberculosis, by which in fact severe forms with cavities could be permanently healed. In a pamphlet of recent date he recommends creasote even as specific for tuberculosis, his recommendations being based upon clinical experience.

In view of this, experimental researches were made at the Moabit Hospital, and these, as well as the experimental investigations of P. Guttmann, Coze and Simon, Sormani and Pellacani, Schüller and finally of Cornet, proved negative in the great majority of cases.

The author points out the importance of appreciating the effects really due to the remedy, in view of the natural variations in the clinical course of pulmonary phthisis, and finds that in a critical inquiry as to its effect upon the chief symptom which reflects the real disease process, *the fever*, the remedy is without any effect whatever, as it is also upon the etiological factor of the disease. No material, lasting change in the presence of tubercle bacilli in the expectoration has been observed in any case; and under the continued administration of large doses of creasote the development of cavities, pneumothorax, amyloid degeneration, etc., has been observed; even in the early stages, the disease has frequently had a rapid course despite the treatment. On the other hand, the accomplished improvements were not greater than those secured under a purely hygienic-dietetic management—a conclusion which is based upon a great number of comparative investigations.

Under the favorable influence of the latter, improvement in the subjective and objective symptoms has been frequently observed in a short time; as for instance in a porter who under three different methods of treatment—tuberculin injections, hygienic-dietetic management, and large doses of creasote, each time gained from eight to twelve pounds in weight in the course of eight weeks in the hospital.

Creasote appeared to act favorably in many cases only through its influence upon the expectoration and digestion.

In common with Th. Weyl, the author demonstrated that the introduction of large doses of creasote into the blood is without influence upon the tubercular process in the lungs; the sputum from such cases having been found fully virulent for animals. Inoculation of such sputum into the anterior chamber of the rabbit's eye was followed by typical tuberculosis, and in all test animals tubercle bacilli were found in great numbers in the iris and cornea.

Intraperitoneal injections upon guinea pigs of sputum from patients who had taken many thousands of creasote pills, were followed by general, miliary tuber-

*Translated from the *Deutsche Medicinische Wochenschrift* for Dec. 15, 1892.

culosis, the latter being confirmed by bacteriological examination.

The results of the investigations which will hereafter be reported in detail in the *Zeitschrift fur Hygiene und Infections-Krankheiten* show beyond doubt, as do also the clinical results witnessed, that creasote is without influence upon the tubercle bacilli, and upon the specific tubercular process in the lungs.

Similar results with the same conclusions were reached in this country by Dr. Karl von Ruck, of Asheville, N. C., who made his investigations in his private institution for phthisical patients, and who speaks of his present employment of creasote in a recent paper as follows: "Creasote is used only for its influence in overcoming fermentative processes in the alimentary canal, when less unpleasant means fail to succeed, and for its stimulating effect upon the mucous surfaces.

I have become absolutely satisfied that creasote has no specific effect upon the tubercular process and have demonstrated that inoculations with tubercle bacilli of blood serum from a patient absolutely saturated with creasote by large and long continued dosage show luxuriant growths of the germs, not differing from cultures in serum where creasote had not been given, also that the germs from such patient's sputum produce virulent cultures."—

SOCIETY REPORTS.

THE MEDICAL-CHIRURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting of December 9th, 1892.

The President, Dr. F. C. Simpson, in the chair.

URTICARIA.

Dr. D. T. Smith : This young man has been in excellent health since childhood, with the exception that he had spasms for a short time during infancy, such as any child might have. These spasms never occurred after he was two years old. He had no other form of illness until he was fifteen years of age, when he had an attack of malarial fever, which lasted two weeks, and after that an attack of typhoid fever.

Before the attack of typhoid fever he felt at one time an itching over the right orbit, and reaching up his hand to ascertain what it was, he felt a tumor about the size of a wine grape projecting. That tumor disappeared, then it came again, this time slightly larger than before, and immediately over the left orbit ; disappearing and again appearing in his ear, then on his cheek, then on his lip, once inside of his mouth ; two or three times on the back of his head, and when I first saw him about four weeks ago, the tumor was disappearing under the right eye.

These tumors are rather soft, except in the middle where there is a little more resistance to be felt. Four evenings ago he felt a twinge just over his right eye, and reaching up his hand felt the tumor coming there. I saw it the next morning. It had then spread some and was projecting probably twice as much as you see now. It comes and goes very quickly—he will simply feel a little itching, put his finger to the spot and the tumor is there. There is no sore upon his skin ; however, there is one little place which does not change, probably a mole, seemingly a little thickening of the skin forming a small lump. He compares these tumors as they pass away to the condition as observed in this spot that does not change.

DISCUSSION.

Dr. Wm. Cheatman : It looks to me more like urticaria than anything else.

Dr. W. L. Rodman : How long do these so-called tumors remain out—that is for what length of time can they be detected from external appearance ?

Dr. D. T. Smith : Sometimes two or three days ; at other times they will appear and disappear in a very short time. Probably the average time is about two days in one place.

Dr. A. M. Cartledge : It strikes me that it is a misnomer to call this condition a tumor. I do not think it can be properly classed as a tumor. When Dr. Smith first described it, I thought it was probably a blood extravasation. I have seen several cases of subcutaneous hem-

orrhage of the scalp which had some resemblance to this case. Since making an examination, however, I think it is neurotic. The case more properly comes under nervous irritation, or a vaso motor paresis.

Dr. A. M. Vance: I believe the trouble is urticaria; I do not see what else it can be; it looks and feels to me like urticaria.

Dr. W. L. Rodman: I am fully satisfied that these swellings are not tumors. The whole history of the case clearly excludes all possibility of tumors or neoplasms. No tumor could grow in so short a time, and disappear so rapidly. I take the view that Dr. Vance does, and am satisfied that it is a disease of the skin.

Dr. D. T. Smith: I agree in the main with what Dr. Cartledge has said: He stated, I believe, that it is vaso motor paresis. I think this enlargement is due to paralysis of the nerves controlling the capillaries and arterioles, allowing an accumulation of fluid in them, mostly blood. At first there is a little discoloration, and finally a very slight ecchymosis, the skin seeming to be involved to that extent. And yet this tumor has appeared once inside of the mouth. While the origin of the trouble is in the nerve control, yet I think it is remotely related to urticaria. Cases of this kind must be very rare, as there is so little record of them. I shall look further and it may be that I shall find some reflex cause. There is no organic change in the brain as shown by the migratory character of the tumor and the trouble must be functional. The reflex may be in the stomach, but I have not been able to find it. I have not examined the nose; however, there has been no complaint. The patient has been in perfect health, and I have been unable to find the least trace of history of any other trouble. I must still denominate this a tumor, though, of course, I am aware it has nothing of the nature of a neoplasm.

Dr. A. M. Cartledge reported a case of Mammary Sarcoma in a Girl of Sixteen Years; Also a Case of Ovarian Cyst. (Page 88.)

DISCUSSION.

Dr. W. L. Rodman: I agree with Dr. Cartledge in what he says concerning his first specimen; I am satisfied from the appearance of the growth and its clinical history there can be doubt as to its malignancy, and, being satisfied of this—whether it be carcinoma or sarcoma—the proper procedure was complete removal.

According to S. W. Gross, the youngest case in which carcinoma of the mammary gland has occurred was twenty-one years. This was in the practice of Henry. His statistics show the youngest case of sarcoma of the mammæ to have been fourteen years of age. One case has been reported to this Society where the patient was not even thirteen years old. I think there is very little doubt about the specimen presented being a sarcoma, and the Doctor did the proper operation, removing the entire breast and cleaning out the axilla.

In reference to glandular enlargements in these cases, I disagree with Dr. Cartledge. While the rule is not to have involvement of the axillary glands in sarcomata of the breast, still there are other exceptions besides the case under discussion. Gross reports several I know. We also know that according to Butlin, sarcomas of glandular organs, especially the tonsil, testicle and lymphatic glands, are more likely to be followed by enlargement of the lymphatic glands than even carcinoma in like situations. The old idea that sarcoma never causes glandular involvement must pass away.

Dr. A. M. Vance: I agree with what has been said, and believe the condition of this tumor was such as to justify complete removal of the breast.

I would like to put on record a case I saw this summer: A very intelligent lady forty-five years of age, consulted me in regard to a tumor of the breast, which was hard and painful at the time. I gave the usual stereotyped opinion that all tumors of the breast in a woman over thirty, ought to be removed, and advised immediate removal. Operation was refused, and I did not see the patient for about a a month, when she again called upon me I made a second examination of the tumor and it was then about half the size it was at the first examination. I will say, however, on the occasion of her first visit to me I advised the removal of corsets, which she had probably been wearing tightly laced, as she was quite a fleshy woman. At the second examination, notwithstanding the fact that the tumor had considerably decreased in size, I still advised its removal. At that time she told me that

she attributed the disappearance of the tumor to the influence of prayer. In another month she returned and the tumor had entirely disappeared, and she wanted me to make a statement that I had examined her on a certain date, finding cancer of the breast; had examined her on another date and found the cancer about half of the size, and again on such and such a date when the cancer had totally disappeared.

This is the first case in my experience where tumor of the breast has disappeared. Dr. Hays will remember another case where the tumor was not in the breast but in the pectoral muscle just anterior of the axillary space. In this case both Dr. Hays and myself thought it was cancer and advised early removal. This patient consulted some "Faith Doctor," and the tumor entirely disappeared.

Dr. W. O. Roberts: I am sorry that I did not hear Dr. Cartledge's report of the tumor of the breast. Of course the younger the subject the more apt it is to be sarcoma. We find many cases of sarcoma of the breast that have gone on for some time, and others which have grown very rapidly with no glandular enlargement in the axilla. I remember one case not very long ago where there was very rapid growth, so rapid in fact, that the physician in attendance took it to be an abscess of the breast and lanced it, evacuating nothing but blood. I afterward removed the growth and found no enlargement of the glands in the axilla. The character of the growth of course influences to a great extent the enlargement of the glands. We have glandular enlargement nearly always in melanotic sarcoma, which goes through the system not only through the blood, but through the lymphatics; we have this sometimes in other forms of sarcoma, but chiefly in the melanotic.

In this connection I would like to refer to the case of melanotic tumor removed from the groin of a very fleshy woman, which I reported some time ago, Dr. Rodman assisting in the operation. Within the last month there has been a recurrence of the disease, there are several tumors on the body but not at the point from which the original growth was removed.

Referring to what Dr. Cartledge has said about the ovarian cyst, I recently reported a case where I operated upon an old umbilical hernia, the patient being an exceedingly fleshy woman and had not suspected ovarian tumor, nor had I, my attention having been directed to the irreducible umbilical hernia. During the operation for hernia the patient had a very severe vomiting spell, a great deal of the intestines protruding through the opening, and I detected a large ovarian tumor, which was promptly removed. My experience is that ovarian tumors are very frequently run across, just as in the case reported by Dr. Cartledge, by accident.

Dr. D. T. Smith: Dr. Douglass Morton used to insist upon a point in reference to removal of the glands in the axilla that seems to me entitled to much weight, that is the danger of recurrence in the axilla was so limited that it did not justify removal of the glands. I notice most leading surgeons, however, are still urging the course recommended by Dr. Cartledge—the removal of all the glands of the axilla at the time the breast is removed, making a complete operation. If it is true that in only three per cent. of the cases cancer returns in the axilla, then it does seem to me that the condition hardly warrants such a complete operation. I saw some time ago a report by Bigelow, I think, of Boston, where he had collected all the cases of cancer of the breast he could find, and only three per cent. of them had recurred in the axilla, all the rest recurring in the scar. In view of this, I think the complete removal of the axillary glands in all cases to prevent recurrence in so small a percentage, is hardly justifiable. I would like to know if any of the members present have any statistics on the subject.

Dr. W. L. Rodman: The best results which have been obtained in the operative treatment of malignant disease of the breast is by a free incision, removing all the glands, and also invading the axilla and removing all enlarged glands and other suspicious tissue. This done we get results second only to operations for the removal of carcinoma of the lip. Dennis' statistics made from a large number of cases of malignant disease of the breast treated by free incision are so good as to approximate in results operations for epithelioma of the lip, the best in the field of operative surgery for malignant disease.

Dr. A. M. Vance: In operations of this character at the Johns-Hopkins Hospital, I observed, while there recently, that they not only cleaned out all the lymphatic glands of the axilla, but also removed all the pectoral muscle on the side affected. Dr. Halstead claims that this is the only way you can hope to entirely remove the cancer. I believe that the wider you go the better it will be.

Dr. A. M. Cartledge: I have very little to say in closing. One point in regard to lymphatic enlargements in sarcoma, carcinoma and other tumors of the breast—there is something in what Dr. Smith says in that it gives a suggestion as to the causation of lymphatic enlargements in growths of the mammary glands. I am a firm believer that originally and primarily many tumors, and very much of the lymphatic enlargement of the axilla, are inflammatory in character from the absorption of pyogenic micro-organisms rather than from metastasis.

In regard to cleaning out the axilla, I think the best way to prove to Dr. Smith that this should be done, is that twenty-five years ago the percentage of recurrence in removal of cancers of the breast was so great, that many of the best surgeons advised against the operation. Later they removed the cancer and the lymphatic glands, and their percentage of recoveries was still greater. Now they go still further than this and remove the pectoral muscles and the results are more satisfactory. I believe that the more structures you remove, within reason, the better the result will be.

Dr. D. T. Smith: It still seems to me hardly necessary or justifiable to remove the pectoral muscles and lymphatic glands in these cases, considering the small percentage of recurrence in the axillary region. In the older operations spoken of by Dr. Cartledge, I am forced to believe that if there had been more complete removal of the cancer itself, the percentage of recurrence would have been much less.

Dr. A. M. Cartledge: If you remove a cancer of the breast ever so thoroughly and then slit up the enlarged lymphatic glands and submit them to a microscopical examination, usually cancerous elements will be found there.

Dr. J. B. Hays read a paper on "Cerebral Syphilis." (Page 86).

DISCUSSION.

Dr. A. M. Vance: I only want to speak of one thing that has been brought up by the paper. My experience proves to me the importance of mercurial treatment in these cases just as much as in the primary stage. I believe that a patient suffering from syphilitic trouble must take about so much mercury before he can be entirely relieved. Though iodide of potassium might bring about the same results, it is a question whether such results would be permanent. While we all know the good effects of iodide of potassium in these cases, it is my opinion that if mercury were given in proper doses from the beginning of the first symptoms, the results would be better and more permanent.

Dr. A. M. Cartledge: I would like to ask Dr. Hays how much mercury he would advise in these cases, and the dose given in these cases, and the cases referred to.

Dr. J. B. Hays: I believe the dose has to be regulated as to quantity by each individual case. I gave in the two cases reported one-fiftieth of a grain.

Dr. C. W. Kelly: I have never given mercury in any stage of syphilis; I much prefer iodide of potassium, and believe this will produce much more satisfactory and more certain results.

Dr. W. O. Roberts: I think in these cases we should push iodide of potassium to the extent that the patient is able to bear it. I had a case of brain syphilis some time ago with Dr. Bodine in which we steadily increased the quantity of iodide until the patient took one and one-half ounces per day—one-half ounce at a dose three times a day. This quantity produced no trouble in the alimentary tract, but he had most excessive duresis, passing enormus quantities of water during the time he was taking these large doses of iodide; it was given very largely diluted. This treatment cleared up the brain entirely; the man is now seemingly in perfect health; has since married and has two children.

Dr. Wm. Cheatham: It is my practice to treat syphilis, in either the first, second or third stage, with a combination of iodide of potassium and mercury. I believe that in brain syphilis mercury given by inunction will produce better results than when given by the stomach.

Dr. A. M. Cartledge: I am satisfied in my own mind that while we all have about

the same things to use in the treatment of syphilis in the various stages, first, second or third, the remedies, mercury and iodide of potassium being the chief, the manner in which we use them has a great deal to do with whether we have success or failure. In those cases where we have deposits pressing upon delicate structures, where it is desirable to remove them very quickly, such as the cases referred to by the essayist, I believe that we get the most rapid results by confining ourselves to the one remedy, iodide of potassium. I think mercury is a valuable agent in syphilis, but there is a difference in the action of these two agents. One point that I desire to call especial attention to is this, that at the same time we are administering iodide of potassium, we should also establish systemic drainage; this can be accomplished by two-grain doses of calomel. I also think quinine may be given in these cases with a great deal of benefit.

Dr. S. C. Dabney: I see a good many cases of syphilis in the tertiary stage, and occasionally meet with the secondary form in diseases of the eye, nose and throat, less often in the ear. In these cases I have used mixed treatment with good results. I will mention as a fact of some interest a case of syphilis I saw recently in which there was paralysis of one of the muscles of the eye within four months after the first inoculation. The occular paralysis developed earlier and more rapidly in this case than it usually does. Disorders of the occular muscles and of the pupils are common symptoms in brain syphilis, but as they did not occur in the cases reported by Dr. Hays, it would probably not be in place to discuss them here.

Dr. D. T. Smith: In my experience I have have only seen one case of brain syphilis; this patient was about thirty-six years of age, a carpenter by trade. Diagnosis was made of cerebral syphilis, which was first noticed by his staggering walk. I had him under observation for nearly three years and think there could have been no doubt as to the diagnosis. He was given large doses of iodide of potassium, probably up to twenty grains three times a day; I also pushed corrosive sublimate up to one-sixteenth of a grain. He went back to his work under my treatment. He fell from a house at one time being pretty badly crippled, which may have had something to do with aggravating the trouble. After that he grew better, then worse and finally became insane and was sent to the asylum, where he died. I believe in these cases of cerebral trouble we may very often be mistaken in the diagnosis, as to whether there is a syphilitic lesion or not.

Dr. C. Skinner: In treating syphilitic cases, I give mercury by inunction preference in the second stage; iodide of potassium in the third and nothing in the first. My reason for giving nothing in the first stage is to be positive about the diagnosis. I use mercury in the second stage by inunction which I think is the best way to give it, keeping the bowels open and saving the stomach. In the third stage I give large doses of iodide of potassium, gradually increasing. I will mention a case of cerebral syphilis in which a man failed to carry out directions, which is just in line with Dr. Hays' paper. I treated this man's wife in an abortion; some time afterward I attended her in a second abortion; then she came to me in her third pregnancy and wanted me to bring about an abortion to avoid carrying the child to full term. Of course I told her I could not do this, but would try and tide her over the critical period. I put her on treatment with bichloride of mercury, in one-thirtieth grain doses three times per day, through the whole period of gestation. She then left the city; returning some time after she again become pregnant, and I treated her in the same way through that period of gestation; a perfectly healthy child was born and now shows no signs whatever of syphilis; the child is now five years old. I give the history of the man: At that time he gave me the history of having contracted syphilis twenty years before. This had apparently been cured, no further symptoms having developed until about two and one-half years ago, when he showed signs of syphilis in his walk, loss of memory, etc.; he said he could not remember anything. I recognized what I thought to be a manifestation of return of the trouble, and put him on iodide of potassium. He improved very rapidly at first, so much that he discontinued the use of iodide and passed out of my notice for a while. Finally he came back to me with a return of the trouble, and I again gave him iodide of potassium, gradually increasing the dose. He again improved and left off the medicine

entirely. I was hurriedly called to his house some time afterward, and found the man in convulsions, and he died in about four or five hours. His wife told me that he had not been taking medicine of any kind for about six months. I have since learned that he discontinued the use of iodide on the statement of the druggist from whom he purchased the drug, that he was consuming a dangerous quantity less, (I think he was taking about four drachms three times per day), and if he did not quit it would kill him.

Dr. J. M. Ray: I have seen a large number of cases of ulceration of the mucous membrane of the upper respiratory passages from syphilis, and must say that I believe iodide of potassium does more good than anything else. It has been my practice to give mercury and iodide separately in these cases. I give iodide for an express purpose, and continue giving it until the desired results are obtained; until the ulcerated surfaces heal up. I continue the iodide as long as I have any local lesion present, then give mercury. I will make here a brief report of an interesting case I saw some time ago. It was a case of syphilis in which there was ulceration of the mucous membrane of the nose with sloughing of the turbinated, and, at the same time, a chancre on the penis.

Dr. J. E. Hays: I have had only a few cases of the kind; I believe two in addition to the ones reported, since I have been practicing medicine. I have never given mercury a trial in any tertiary lesion, excepting in the last case referred to in the paper. I must say, however, that iodide of potassium has never failed in a single instance. I believe that is the best known remedy in removing syphilitic infiltrations. I simply gave mercury in this case as an experiment, not having very much faith in its efficiency. I believe, like some authorities, that if mercury would destroy the germ of syphilis, if given early, we could do away with all these latter manifestations, that is, the so-called tertiary symptoms.

CORRESPONDENCE.

REVIVAL OF "HEATONISM"; HERNIAL INSTITUTES AND SUBCUTANEOUS INJECTION FOR HERNIA.

Editor Medical and Surgical Reporter:—We have recently seen through an exchange, (the New York *Medical Journal*, Jan. 7th, 1893,) that "Heatonism" and rank, downright quackery has again invaded the domain of Hernial Therapeutics. This time, however, in a more bold and defiant manner than Heaton ever dreamed of; for he published his wonderful (?) cure in the public press only.

In a nutshell, we are told by Dr. Wm. C. Kloman, of Baltimore, that a new method of treating hernia by the hypodermic injection of irritant solutions has enabled him to cure chronic old herniæ, which have been previously irremediable; that the method was equally successful in both sexes at the Institute (?) and that it was even equal to the cure of strangulated hernia.

Now, the most preposterous assumption, in connection with this so called, new nostrum, is the claim that the wonderful discovery belongs to Dr. Chas. McCanless, of Atlanta, Ga.

This may pass when addressed to those who know little or nothing of hernial literature; but to those of us who have, at least a rudimentary acquaintance with that part of the history of our art, it certainly is news. Nevertheless, in all fairness, to the memory of Boston's notorious hernial quack, we are bound to ask for information and beg to know in what particular the new (?) method differs from Heaton's injections?

Aye! It not only is Heatonism reproduced as far as technique goes; but it smacks further of methods of Heaton inasmuch as it does not state in the article above cited, what is employed as an injection-menstrum.

Is it intended, Koch-like, to withhold the great secret until its utter worthlessness is shown; or, like Prince Mattei, carefully guard its secrecy against the whole world?

It is not generally known that Dr. Heaton, of Boston, was the first who ever employed invagination of the hernial sac, and employed subcutaneous injections along the inguinal canal on a large scale for hernia. And he claimed he could cure all reducible herniæ. He, however, never pretended that he could treat a strangulated hernia in this way. The whole world stood amazed at his wonderful cures (?)—these cases in which a patient after spending a month in bed got up with his hernia remaining out of sight so long as a truss was worn;—which permitted him time enough to write out a testimonial to the doctor. But the old gentleman was finally prevailed upon to write a book or to supply the data for one. This he did; when the whole thing fizzled out and the world, at last, saw the secret, that the mystery was the talisman, and that the whole thing was little else than a piece of downright imposition.

If something has been discovered which will cure certain varieties of hernia, by all means give the world the benefit of it; but don't thrust on us, as a new discovery, a revamped relic of Boston Quackery.

VERITAS.

False Neurasthenia.

Dr. Myrtle writes as follows upon this subject: "We may find symptoms in every respect similar to those of true neurasthenia, and it will take you all your time and patience, as well as tact, to detect the sham from the real. If you look back a bit, you will find that as a child she showed temper; as she grew, she became fitful, hysterical, and given to the sulks; craved for sympathy, and exhibited little or no sympathy for others. On questioning her, she describes her sufferings in forcible language. She can neither eat nor sleep; has not an atom of strength; suffers from the most dreadful pain, most fearful headaches, and frightful spasms, and should you suggest any portion of her body from her head to her heels, as possible exempt from pain; she often resents the insinuation, and declares that is the very part where she suffers most. While she tells you all this in a sort of whine, her features don't show indications of any agony, and, if you watch her, you will find that she overacts her part. Utterly indifferent to the anxiety of parents and friends, or to the trouble and expense she causes, she seemingly finds gratification in watching the unwearied efforts of those around her in doing their best to comfort and help her. While putting on an air of the most abject listlessness while you look at or speak to her, if you talk to her you will learn that she has both eyes and ears; if you assist her in any way she makes herself as helpless as she can—a dead weight. These creatures not only deceive every one around them, but in time they succeed in deceiving themselves. Were it not so, I cannot understand how they continue playing such a sorry game for so long, and with so much strain and fixity of attention, to the exclusion of everything else, as I have seen them do. If we push our inquiries a little further, we generally discover that there is some ocliquity of the moral sense; an ungratified whim or disappointed affection at the bottom."—*Ex.*

Thiol in the Treatment of Burns.

Bidder (*Archives fur Rhinische Chirurige*) says that in treating burns a dressing should be selected which has the following qualities:

(1) Should not require frequent changing.

(2) Relieve pain.

(3) Act as a drying substance.

(4) Harden the new skin.

(5) Hinder the growth of micro-organisms which may have gained entrance to the wounded parts.

The remedy which he has found to possess all the sequalities is *Thiol* which may be used in two forms, liquid and powder.

In burns of the first and second degree, where the blebs are still intact, it is only necessary to brush the burned area with equal parts of liquid thiol and water and cover with wool. At the end of eight days the dressing should be changed, and again re-applied if the blebs have not healed. If the blebs have been ruptured and the corium exposed, all loose skin should be cut away and the burned area carefully cleaned; it should then be brushed with liquid thiol, and powdered with salicylic or boric acid and then with powdered thiol, and the whole covered with vaseline, cotton wool, and bandaged. As a rule, one or two dressings are necessary before the wound has healed.—*Ex.*

The Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JANUARY 21ST, 1893.

EDITORIAL.

THE QUARANTINE PROBLEM.

There is always much gained when an important measure reaches the point of serious discussion. There is then hope for common sense conclusions. The discussion of the very important question of a National Quarantine is taking practical form in the halls of our National Congress, and there is an assured promise that a measure, bearing the *ear marks* of practical statesmanship, will be adopted.

The question is not one limited within the corporate lines of any city or the bounds of any one state. It is one broader even than our national domain. It should be treated nationally, distributing the burden of an effective quarantine over the entire people, thus mitigating features that would otherwise prove oppressive to distinct communities.

The difficulty of building efficient barriers against Asiatic cholera is recognized by all scientific men. The inefficiency of local quarantine was thoroughly demonstrated last summer. The quarantine at New York was as efficient as it was possible to make it with inadequate means, imperfect methods and the discreditable jealousies of officials, yet it did not keep the cholera out of New York City. There may be pestilence in politics but there are no politics in pestilence. The opposition of local or city health authorities to those of the Federal quarantine was forcibly illustrated by many little episodes in New York's experience.

A notable fact was, that after the issue of the President's proclamation of national quarantine, no passenger vessel brought a case of cholera to this country. It had the good effect of enforcing more care abroad. It was a warning that crossed the Atlantic—a notice to all passenger carrying steamships that American ports were closed to all vessels carrying pestilence and that they would remain closed until all danger was passed.

There is a provision of our Federal Constitution which imposes upon Congress one of its highest and most sacred duties, that is, to "provide for the common defence and general welfare of the United States." We take it that the general health comes within the provision for the "general welfare," and that this clause gives the power

to establish a system of rigorous, and as far as human measures are possible, effective quarantine.

Dr. Watson, chairman of the International Quarantine Committee, reported that there is not a single port on the North Atlantic coast that is supplied with all the requisite means and methods of modern maritime sanitary science. He gave to Philadelphia the credit of being the best supplied of any port in the country.

Certainly our experiences, modern science, the stimulus of recent menaces of pestilence, have substituted greatly improved for antiquated methods,—importers and reporters to the contrary notwithstanding.

The question of the further improvement of methods and appliances and their efficient application is the one that at present most concerns American communities.

Reason and humanity dictate that we use every device and method approved by science and experience in protecting the public health. Our precautions should be taken before we are confronted by conditions of terrible peril; they will be too late when pestilence has secured a foothold.

A double quarantine is not objectionable. To approach completeness it should be both local and national, with the hearty and vigorous coöperation of all authorities to whom the work may be intrusted.

With a coast as extended as ours, cases will be likely to break through however vigorous the quarantine may be. The Federal authorities will have in their possession the better means and facilities of enforcing essential measures, and will command more respect than can or will local authorities. This respect would the more specially be felt abroad and would further have the good effect of keeping away from our shores a very undesirable class of people. Local resources are often limited, and there is a lack of the implements or plants for adequate and quick disinfection.

The effective guarding of the country against epidemics necessarily involves many risks and hardships. The distress of a stringent quarantine must, in the very nature of things, be seriously felt in all trade and commercial centres. This fact presses the importance of placing the discharge of all the duties of quarantine authority in the hands only of men of the highest character and intelligence; men wise, quick and prompt in the discharge of duty, and that without fear or favor; men above the motive of selfishness, of local or trade jealousies. Neither the interest of the individual, nor of any class of individuals, nor of any one or more communities should be allowed to stand in the way of the "general welfare."

While there exists no reason for undue alarm, neglect to take precautions against the possible visit of an epidemic would be crime. Philadelphia has had three visitations of Asiatic cholera, 1832, 1849, 1866, and has no assurance of exemption in the future. The responsibility vesting upon our local authorities cannot by them be over estimated.

Cleanliness is the one great foe of cholera. Filth has many lurking places and should be routed out and destroyed. Every disease breeding hole and corner should be disinfected. Active practitioners of medicine can exercise a potent influence in this line. They have been made painfully familiar with the causes of many of the terrors with which they have to deal—they know where lurks the fruitful source of pestilence, and, where they will to exercise it, they have an effective voice in its removal. Diligent efforts in the way of sanitation should be made in every city, town and village. In our own city, health, good morals, great trade and commercial interests are involved, and *cleanliness* will do as much,

if not more for us, than quarantine with its embarrassing restrictions.

It has been estimated that a complete quarantine will eliminate seventy per cent. of the probability of the introduction of cholera. Certainly the other thirty per cent. can be prevented by cleanliness and the practice of the best known principles of preventative medical science.

London, the great commercial centre of Europe, toward which tend all the roads of the old world, had but ten deaths from cholera in 1892. In our own city the deaths from diphtheria have doubled and quadrupled that number in one week. Our house cleaning will keep out the foes of public health.

The Senate Bill places the matter of national quarantine where, under existing conditions, it should be. There is no more intelligent, scholarly and scientific a set of men in the country than the medical authorities in the marine service.

The following from the Report of the Senate Committee in epidemic diseases, is worthy of thoughtful reading:

"The committee is satisfied that an effective and uniform system of quarantine regulations vigorously enforced at all ports and places having commercial intercourse with foreign countries is absolutely necessary as the only means of preventing the importation of contagious and infectious disease into this country from other countries, and that a perfect and uniform system is equally necessary to prevent the importation of such diseases into one State from another.

Some of the States have adopted systems of quarantine regulation which, in the opinion of the committee, are sufficient, so far as treatment at the port of entry is concerned; but many others have no quarantine regulations whatever, and if a single gate is left open to the introduction of such diseases the whole country may suffer the disastrous consequence of fatal epidemics.

Scientific investigation has asserted that neither yellow fever nor cholera originates in this country, but that if either is imported, under certain atmospheric conditions they will take root and spread with disastrous rapidity and fatality.

The most important of all considerations is to keep them out, and in the opinion of the committee the only means of effectually preventing their importation is a thorough system of national quarantine, which shall be uniform and enforced with vigor at every point of intercourse with foreign nations, and equally uniform and equally enforced as between States.

State quarantine authorities have been jealous of any interference by national authority with their quarantine regulations, and those of New York and New Orleans have heretofore steadily opposed any national control of the subject.

The quarantine regulations of these States give a large revenue to these States or to their boards of health, and for that reason, if for no other, they may be expected to oppose national control.

Now, however perfect their systems of regulations and the systems of other States may be, they are but the systems of a small proportion of forty-four States.

The forty-four States need, demand, and are entitled to protection from this importation of disease.

The eighth section of article one of the Constitution of the United States provides that—

Congress shall have power to regulate commerce with foreign nations and among the several States and with the Indian tribes.

The regulations proposed by this bill are strictly regulations of foreign and interstate commerce and nothing more.

The transportation of a person or any article of merchandise from any foreign country to this country, or from this to any foreign country, is an act of "commerce with foreign nations," and the transportation of persons or property from one

State to another is an act of "commerce among the States."

This bill proposes to so "regulate commerce with foreign nations and among the several States" as to strip it of contagion and infection.

NATIONAL QUARANTINE.

The Quarantine Bill passed by the United States Senate, Tuesday, January 10th, consists of ten sections of carefully framed legislation which seem to us to provide reasonable security for the public health from the invasions of infectious or contagious diseases. It provides for medical inspection of all vessels both at the port of departure and that of entry, and requires from each a clean bill of health, thereby protecting the country against infection from abroad. It authorizes the establishment of quarantine as between the States, so that if such disease should effect a landing, its progress may be stayed. It abolishes the National Board of Health, and puts the whole subject under the control of the President of the United States, with ample power for needful details in the hands of his Subordinate, the Secretary of the Treasury, thereby making prompt action possible in any emergency. It provides for adequate penalties for the violation of the law or of any regulations established under it; and appropriates $1,000,000 to carry its provisions into effect, thereby, putting power behind all its provisions.

RESUME OF MEDICAL PRACTICE ACTS IN THE DIFFERENT STATES AND TERRITORIES.

In response to numerous requests we give the following, taken from *Medical Education*, etc., published by the Illinois State Board of Health, 1891.

ALABAMA.—Examination by the State Board of Examiners, or by a County Board of Examiners. Law passed in 1877.

ARIZONA.—Register diploma with County Recorder. Passed in 1881.

ARKANSAS.—Registration of diploma or examination by the State or a County Board of Examiners (latter inoperative). Law passed 1881.

CALIFORNIA.—Certificate on diploma from a college in "good standing" or examination by one of the three Boards of Examiners. Passed in 1876.

COLORADO.—Certificate on diploma of college in "good standing" or examination by the State Board of Medical Examiners. Passed in 1881.

CONNECTICUT.—No law except against advertising itinerants.

DELAWARE.—Registration of diploma in a County Clerk's office. Passed in 1883.

DISTRICT OF COLUMBIA.—Endorsement of diploma or examination by committee of the District Medical Society (practically inoperative). Passed in 1838.

FLORIDA.—Examination by one of the State or District Boards of Medical Examiners. Passed in 1884, 1889.

GEORGIA.—Registration of diploma in the office of the Clerk of the Superior Court. Passed in 1881.

IDAHO.—Record diploma at county seat. Passed in 1887.

ILLINOIS.—Certificate on diploma from college "in good standing" or examination before the State Board of Health. Passed in 1877, 1887.

INDIANA.—Registration of diploma in County Clerk's office. Passed 1885.

INDIAN TERRITORY.—(*a*) Cherokee Nation: Examination by the Board of Examiners of the Nation. Passed 1878. (*b*) Choctaw Nation: Certificate on diploma or examination by the Board of Examiners of the Nation. (*c*) Creek Nation: No law.

IOWA.—Certificate on diploma from college "in good standing" or examination by the State Board of Medical Examiners. Passed 1886.

KANSAS.—No law.

KENTUCKY.—Ten years' practice, or registration and endorsement of diploma of a legally chartered college by Secretary of the State Board of Health. Passed 1874, 1888, 1890.

LOUISANA.—Recording diploma before County Clerk or Justice of the Peace after endorsement of same by State Board of Health, which is "required to certify to the diploma of any medical institution of credit and respectability without regard to its system of therapeutics." Passed 1882, 1889.

MAINE.—No law.

MARYLAND.—Verification of diploma of "college in good standing," or examination by State Board of Health (law inoperative). Passed 1888.

MASSACHUSETTS.—No law.

MICHIGAN.—Record diploma in County Clerk's office. Passed 1883.

MINNESOTA.—Examination by State Board of Medical Examiners. Passed 1883, 1887.

MISSISSIPPI.—Examination by a County Board of Medical Censors. Passed 1882.

MISSOURI.—Certificate on diploma from college in "good standing" or examination by State Board of Medical Examiners. Passed 1883.

MONTANA.—Ten years' practice, certificate on diploma from a college "in good standing" or examination by State Board of Medical Examiners. Passed 1889.

NEBRASKA.—Register in the office of the County Clerk. Passed 1881, 1883.

NEVADA.—Register diploma before the County Recorder. Passed 1875.

NEW HAMPSHIRE.—License from the Board of Censors of Medical Society.

NEW JERSEY.—Examination by the State Board of Medical Examiners. Passed 1880, 1888, 1890.

NEW MEXICO.—Endorsement of diploma or examination by Territorial Board of Examiners. Passed 1882.

NEW YORK.—Examination by one of the State Boards of Examiners, after September 1, 1891. Endorsement of diploma until September 1, 1891. Law passed 1880, 1888, 1890.

NORTH CAROLINA.—Examination by the State Board of Medical Examiners. Passed 1859, 1885.

NORTH DAKOTA.—Examination by the State Board of Medical Examiners. Passed 1890.

OHIO.—Law inoperative.

OREGON.—Certificate on diploma from a college "in good standing" or examination by the State Board of Medical Examiners. Passed 1889.

PENNSYLVANIA.—Registration of diploma before County Prothonotary after endorsement (of diploma from college outside of State) by some Medical College within the State. Passed 1881.

RHODE ISLAND.—No law.

SOUTH CAROLINA.—Examination by the State Board of Medical Examiners. Passed 1881, 1888.

SOUTH DAKOTA.—Certificate on diploma, or examination by the Territorial Board of Health. Territorial law 1884.

TENNESSEE.—Registration after certificate on diploma of college "in good standing" or examination by State Board of Medical Examiners. Passed 1889.

TEXAS.—Registration after endorsement of diploma, or examination by a District Board of Examiners (practically inoperative). Passed 1876, 1879.

UTAH.—No law. (*Recent enactment requiring examination not at hand.*—ED.)

VERMONT.—Registration after endorsement of diploma, or examination by a Board of Medical Censors appointed by either State Medical Society. Passed 1880.

VIRGINIA.—Examination by State Medical Examining Board. Passed 1884, 1888.

WASHINGTON.—Examination by State Medical Examining Board. Passed 1890.

WEST VIRGINIA.—Certificate on diploma of "reputable" college, or examination by the State Board of Health. Passed 1882.

WISCONSIN.—Examination or endorsement of diploma by the censors of any State or County Society. Laws of 1878, 1881.

WYOMING.—File record of diploma with Registrar of Deeds. Passed 1886.

In Minnesota, Montana, North Dakota and Washington every applicant for license to practice must have attended three courses of lectures. The same will be required by the California Boards after April 1, 1891; the Colorado Board after July 1, 1893; by the Illinois and Iowa Boards after the session of 1890–91 and by the Boards of Examiners of New York after September 1, 1891. There will probably be three more State Examining Boards in the next year.

TRANSLATIONS.

GONORRHŒAL INFECTION—MODES OF EXTENSION.

There is no doubt that blennorrhœa in women is of more frequent occurrence than is generally accepted and that its results are more extensive than was formerly taught. It has been shown that blennorrhœa in the female can involve the entire genital tract—the uterus, tubes, ovaries and even the neighboring peritoneum may be attacked by acute inflammation. It has also been shown that women in the first days of their married life have been infected by their husbands, who, since they had no discharge, had been declared by their physicians to be cured, or who married when they themselves felt satisfied they were no longer diseased. In this manner many young women begin to suffer more or less from the early days after marriage to the end of their natural life. Menstruation becomes abnormal; the uterus and its adnexa undergo inflammatory changes; the wife may abort frequently or remain sterile, or she may bear one or two children, and the puerperium may be complicated with inflammation.

A large number of such unfortunate women present themselves to us and often try our patience to the utmost. They frequent the various sanitaria and markedly increase the percentage of the nervous hysterical women. Their sterility, from the social standpoint, is really deplorable, since large families die out and the population is much influenced. That women so affected can still become pregnant no one doubts, but that blennorrhœa produces pathological changes in the uterus,

*Translated for MEDICAL AND SURGICAL REPORTER.

tubes and ovaries has been demonstrated also beyond a doubt.

In relation to the diagnosis and course of this disease the author differs from Zweifel, Saenger, Fritsch and others. It is remarkable that these eminent men have, by various theses, explained the origin of blennorrhœa as accepted to-day in almost the same words as those of Nœggerrath; and we to-day understand the etiology of the microbes of blennorrhœa. According to their investigations, blennorrhœa in the male will exist a long time after infection without any symptoms being present. This is termed latent blennorrhœa and will induce in the female also a latant blennorrhœa, which may not produce any symptoms for months, oft times none, until marked disease of the uterus and its appendages attracts the attention of the physician. In such the secretions show no gonococci.

Dr. Feleki contends that latent blennorrhœa exists neither in the male or female, but that the male may have an urethritis of either a contagious, acute, or chronic character, or no blennorrhœa; or he may have, resulting from an old blennorrhœa, the pathological changes which cause the urethritis.

Inflammation of the urinary tracts of an infective character in the male, even if of some years standing and showing no discharge, will produce in the female a typical, not latent, attack of blennorrhœa. The definite diagnosis of blennorrhœa in chronic cases can only be secured when gonococci are found in the secretions or urine.

In the inital stages of blennorrhœa, gonococci are always found; and in the chronic stages, they are always present, except in those cases where the catarrh is no longer present, but pathological changes can be thoroughly demonstrated, or where other affections are present which change the character or cause of the secretion.

The author having studied this subject for several years has arrived at the following conclusions:

First. Chronic blennorrhœa in the male, even if no other symptoms are present, has the occasional appearance of gonococci in the urine, and will produce in the female a typical attack of blennorrhœa.

Second. If the secretion from the urinary passages of the male contains no gonococci, there will be no direct attack of blennorrhœa in the female.

Lastly the author calls attention to an affection which has received very little study of late, namely, pseudo-gonorrhæa. It is known that an infectious urethritis can exist in the male, the secretion of which will show no gonococci throughout its course. It is questionable whether this appears in the female. As facts directing the attention to this point the author cites Ophthalmo - Blennorrhœa Neonatorum. Investigation has shown that this disease from its etiology and course could be divided into two groups. In the group which could be classed the severer, the gonococci could be found in the secretion, while in the cases of lighter form the microbe could not be found. The question naturally arises if in these lighter forms the cause was that of pseudo-gonorrhœa.—(*Wiener ärztl. Centr.—Auz.*)

Vermiform Appendix Containing a Foreign Body Found in a Hernia.

H. Schmidt (*Münch Med. Wochen.*, 1892). The vermiform appendix is rarely found within a hernia, but few cases having ever been recorded in medical literature. The author reports one case. A woman aged 53, who had a right inguinal hernia of recent origin, which became inflamed, and after a few weeks opened and discharged blood, pus, and fecal matter. During the operation Schmidt found a hernia sac in which was caught a vermiform appendix—along the side of this a sound could be readily passed into the abdominal cavity.

The hernial sac was removed and its opening closed. Complete recovery. Close examination of the removed vermiform appendix disclosed the presence of a large black pin.

Personal Experience in the Operative Treatment of Ruptured Tubal Pregnancy.

(*Berlin Klin. Wochen, 1892.*) Gusserow gives a report of twenty cases operated upon by him. In thirteen of these there had been no premonitory symptoms previous to the collapse brought on by internal hemorrhages, while in seven there had been a formation of an hematocele previous to the dangerous hemorrhage which called for operation.

In the first group of thirteen there were two deaths. One due to collapse, the operator having been called too late. The

other died thirty days after from chronic disease of the kidneys.

In the second group of seven cases there was one death.

Gusserow advises, as a result of his experience, operation for all cases of ruptured tubal pregnancy. He would not hesitate to have a patient in collapse taken to the hospital for operation. Prognosis is always more favorable the earlier the cases are recognized and operated on.

In closing his remarks he expresses himself in favor of operation on such cases in which the diagnosis is clear, previous to rupture, but adds that sure diagnoses are ofttimes difficult, since a small ovarian cystoma lying close to the uterus might be taken for tubal pregnancy. In such cases he advised placing the patient under careful and close observation, absolute rest and expectant treatment, in order to determine if the uterus or the tumor increases in size. It is of yet greater difficulty to determine whether the ovum in the tube still lives or not: a question which materially influences the operator in deciding upon prompt interference.

ABSTRACTS.

THE ADMINISTRATION OF CHLOROFORM, AND ITS DANGERS.

In an address before the Inter-colonial Medical Congress of Australasia, Dr. James Robertson, President of the Section in Medicine, says:

The vital importance of the subject, the frequent occurrence of fatalities, and the conclusions arrived at by the Hyderabad Chloroform Commission, which he regards as fraught with danger, induced him to select this subject.

The administration of chloroform—the most potent and valuable of anæsthetics—is to be regarded as one of the most responsible duties devolving on a medical man; seeing that the life of a human being is at stake, and its sudden termination is dependent, in a great measure, on his care and vigilant circumspection. Notwithstanding the numerous attestations in favor of chloroform, many in doubt and distrust are adopting the use of ether.

No anæsthetic can be said to be absolutely free from danger, but with judicious care and caution the risk may be reduced to a *minimum*. Chloroform has been well described by Dr. Lauder Brunton, as being "like a sharp knife in the hands of the surgeon, as compared with a blunt one. It is more efficient for good, if properly handled; it is more powerful for evil, if misused." Ether, it must be allowed, is less dangerous than chloroform, in not causing so much depression of the heart's action, but it is unpleasant, irritating to the air-passages, cannot be used under certain circumstances or in every case.

Chloroform maintains supremacy as the most "pleasant, speedy, and efficient" anæsthetic, requiring no special apparatus, suitable in every case fit for operation, and safe when given with judicious care. Its advantages are such, that it has been generally adopted in preference to all other anæsthetics, and is still regarded with most favor.

In 1888, and again in 1889, Commissions were appointed by His Highness the Nizam of Hyderabad, at the request of Surgeon-Major Lawrie, to investigate the action of chloroform. The philanthropy of His Highness, in liberally supplying funds for the experiments, and the expenses of an expert sent from England, cannot be too highly appreciated, the laudable object of the commission being, in the words of the Nizam, "to save people's lives." The commission, after the sacrifice of hecatombs of dogs and monkeys, arrived at the conclusions, that, "in every case where chloroform was pushed, the respiration stopped before the heart," and that "the administrator should be guided as to the effect entirely by the respiration." The numerous experiments and their record manifest careful and laborious investigation, and merit the thanks of the profession, but the conclusions arrived at cannot be accepted as applicable to human subjects. The result of the experiments has been to direct attention to a subject of vast importance, and to arouse inquiry, which cannot be otherwise than beneficial.

My experience of the administration of chloroform extends from the year of its introduction by Professor Simpson, 1847, the year in which I myself commenced practice. For nearly forty-five years I have exhibited that anæsthetic in many thousand cases, often in prolonged operations, and never with fatal consequences. I refrain from reducing the number to figures, as I cannot even give a close approximation to it. In not a few instances, alarming and even dangerous symptoms have presented themselves, and have strongly impressed me with the risk of trusting alone to respiration as the index of danger. I have watched both pulse and respiration, and ultimately came to regard the state of the pulse as the first signal of danger. I have no new experiments to lay before you, but I shall endeavor to demonstrate, from the experiments of others, and from clinical observation and experience, that the state of the pulse is not of less importance than the state of respiration, as an indication of danger in the administration of chloroform; that it is, indeed, the earliest and most significant danger signal.

Different individuals are differently affected by chloroform inhalation, and this may be accounted for by constitutional peculiarities. Some inhale quietly, and are speedily brought under its influence; some become excited, and toss their extremities about; while others resist and struggle violently. This, however, may be due to the mode of administration.

It is very generally urged, that the pulse should not be taken as any guide in the administration of chloroform; that the respiration alone demands attention. This contention seems to be strengthened by the Report of the Hyderabad Commission, to the effect that, in animals respiration always stopped before the heart, and that all danger can be averted by attending to the respiration alone. Although I do not decry the results of experiments on the lower animals, inasmuch as they afford most valuable indications, I object to hard and fast lines being drawn, and hesitate to accept the dictum, "that the effects of chloroform are identical in the lower animals and in the human subject." It is well known that the effects of various drugs differ much, more especially of narcotics, when administrated to the lower animals and to man. The lower animals are not capable of being influenced by the same feelings and emotions as man, and, according to the testimony of the Hyderabad Chloroform Commission, operations liable to produce shock and syncope in man, were singularly devoid of effect in dogs. The effects of chloroform are not uniform in different human individuals, even when administered in the same way, and in certain definite proportions, or even in the same individuals at different times. According to the experiments of the Hyderabad Chloroform Commission, respiration always fails before the circulation, and there is no such thing as chloroform syncope. Experiments on animals reported by other Commissions, "the Royal Medico-Chirurgical Society's Committee of Inquiry," and "the British Medical Association's Committee on Anæsthetics," negative to some extent the conclusions of the Hyderabad Chloroform Commission, showing that, while in most cases the respiration stopped before the heart, sometimes both respiration and the heart's action failed simultaneously, and sometimes the heart failed before respiration. The testimony of other observers is not less adverse. Dr. Snow, forty years ago, showed that, in animals killed by chloroform inhalation, when the air contained not more than 5 per cent. of vapor, the heart continued to pulsate when respiration had ceased. When the air contained 10 per cent. and upwards, death took place more speedily, respiration and circulation ceasing at the same time, there being sufficient vapor in the lungs at the moment the breathing stopped to paralyse the heart, as soon as it was absorbed and added to that already in the blood. This, he terms its cumulative property, when the effects of chloroform increase after discontinuance of inhalation.

It appears that the most immediate effect of chloroform on the heart, or on the respiration, was influenced by the more or less concentrated state in which it was administered. But, even were it proved that chloroform invariably causes death in animals by paralysing the respiration, we have the most positive evidence that failure of the heart's action is the most frequent cause of death in man. An overwhelming amount of evidence has accumulated, and still continues to accumulate, since the first recorded death from chloroform in 1848, to the effect that the

occurrence of death in the human subject is almost invariably due to primary failure of the heart, or syncope. Such is, indeed, the principal source of danger, and it is a remarkable circumstance that a diversity of opinion should exist in regard to a question capable of definite solution.

Clinical experience goes to prove that death from failure of the heart is the usual source of danger in the human subject, and is especially liable to occur when the vapour of chloroform is inhaled in a concentrated form, or insufficiently diluted with air. The records of the numerous fatal cases reported in the various medical periodicals conclusively attest that death from syncope is the most common termination in man. For not only have the deaths been attributed to failure of the heart, but in cases where *post-mortem* examinations were made, such lesions have been described as "fatty heart," "flabby heart" "heart dilated," &c., &c. It is well known, however, that in many, if not in most, cases, where death has supervened, no lesion of heart, or of any other organ, has been discovered—that, in fact, the syncope was due to chloroform poisoning.

THE INDICATIONS AND SOURCES OF DANGER OF CHLOROFORM NARCOSIS.

The period of greatest danger appears to be at the commencement of inhalation, before the patient has been thoroughly brought under its influence, and not during the progress of even a prolonged operation. It has been stated that the danger of failure of the heart's action, from the depressing effect of chloroform, depends on, and is in proportion to the length of time of inhalation, and consequently of the operation. This, however, is not the case. If chloroform is given sufficiently diluted with fresh air, and respiration continues normal, the vapour of chloroform is exhaled, as well as inhaled, and the blood does not become so saturated, as to endanger the heart. The danger is, in a great measure, dependent on the amount or degree of concentration of the vapour inhaled; as the vapour, if inhaled insufficiently diluted with air, affects the heart more directly, and may lead to sudden paralysis of that organ.

The immediate causes of death in chloroform toxæmia, are syncope, and apnoea. In the large majority of cases, death takes place from sudden syncope in the human subject, due to paralysis of the heart.

Death may also result from syncope brought about by the combined effects of sickness of stomach, and the depressing influence of chloroform on the heart. This stomach sickness, or nausea, has been stated "to be only unpleasant and inconvenient, desirable to avoid, but not attended with any danger." It has, however, proved a real danger, inasmuch as in not a few cases, suffocation has been induced by food being drawn into the glottis during the effort of vomiting. But apart from this, when there is no food in the stomach, there is, in my opinion, a real danger attending sickness, unless the pulse is watched. I have frequently observed the pulse became slow and weak, and the lips blanched, and have thus been led to withdraw the chloroform instantly, and then the faintness was followed by vomiting. If, instead of withdrawing it, chloroform had been pressed, as I have somewhere seen advocated "to stop the contractions of the stomach," it might have resulted in stoppage of the heart's action. I am strongly of opinion that, when a patient is in a fainting condition, even a small dose of chloroform may so affect the heart, as to cause complete cessation of its action, and that the pulse gives the first indication of danger, the first warning, respiration if at all, being but little influenced.

Deaths from apnoea are only occasionally met with. They arise from spasms of the glottis and diaphragm obstructing the respiration, and are sometimes attributed to reflex action in some operations (ligaturing hemorrhoids, etc.), when the patient is not thoroughly anæsthetised. Apnoea is sometimes attributed to the tongue falling back and occluding the glottis, when a patient is lying on the back under the influence of chloroform narcosis; from this source, I have never seen any cause for alarm.

PRECAUTIONS TO BE OBSERVED IN ADMINISTERING CHLOROFORM.

It will be readily admitted that the chloroformist should give his whole attention to his patient; should see that the chloroform is pure; that the patient has not recently eaten food; that he is placed in the recumbent position, or in such a position as not to obstruct respiration, all

articles of clothing being loose about the neck, chest, and abdomen. I regard the use of table-napkin or towel folded in the form of a cone, with or without an aperture at the apex, such as was originally proposed by Professor Simpson, as well adapted for the purpose. One-half to a drachm of chloroform should be sprinkled on the napkin as required, so as not to moisten the border likely to come in contact with the face.

In commencing inhalation, always allow sufficient space for the free admission of atmospheric air, so that the vapour may be diluted, and its effect may be gradually produced, so as to avoid exciting cough or struggling. Allowance should be made in the warm season of the year for the effect of temperature in rendering chloroform more volatile, and thus causing the air to become more saturated with the vapour. Patients should be gradually brought under the influence of chloroform until its full effect is produced, and then very little chloroform will be required to maintain insensibility. The vapour may be diluted with more air, by withdrawing the inhaler to some extent, or inhalation may be intermitted for two or three inspirations occasionally.

The state of the pulse should be carefully watched; it gives the first indications of danger. When the pulse becomes weak and slow, perhaps irregular and intermittent, fresh air should be freely admitted; when, moreover, respiration becomes shallow and feeble, perhaps stertorous, the inhaler should be withdrawn altogether for a short time. In prolonged operations, special care should be taken that the vapour inspired is sufficiently diluted with fresh air, so as to guard against sudden syncope, the most frequent cause of a fatal termination in the human subject.

MEASURES TO BE ADOPTED IN SUSPENDED ANIMATION FROM CHLOROFORM.

The head should be lowered and feet elevated, and artificial respiration commenced without delay, fresh air being freely admitted, and any obstruction to respiration removed. Nelaton's plan of inverting the body, and artificial respiration, are without doubt most conducive to resuscitation in chloroform poisoning. By this means the blood will gravitate towards the head, and the action of the heart may be roused to contract, and send a supply of blood to the brain and medulla, so as to stimulate the cardiac and respiratory centres.

No successful issue has followed the employment of galvanism that I have heard of; and certainly, not more benefit can be expected to result from nitrite of amyl inhalation, which causes dilatation of the peripheral blood-vessels, a condition already existing to the fullest extent, and which it is desired to remedy. Nitrite of amyl is therefore contra-indicated. The injection of ether subcutaneously, or of ether and strychnine, is more rational, and likely to prove of benefit, artificial respiration being kept up. Mr. Bader (Ophthalmic Surgeon, Guy's Hospital) states that, "out of a large number of cases (3224), some presented serious symptoms, becoming blue in the face, with stertorous breathing and irregular pulse, seven became pale suddenly, with respiration and pulse stopping. In all these cases the chloroform was removed, and the patient slowly and gently turned to the left side. Patients recover rapidly when placed on the left side, due, it may be, to the support given to the heart, or to a change in the position of the tongue." This, he states, is the sole means adopted at Guy's for the last six years.

The Marshall Hall method failing to restore animation in a desperate case, Dr. Prince, (Illinois State Medical Society, 1891,), adopted a new method of resuscitation based on Nelaton's method of inverting the body:—He seized the patient, a boy of 14 years, by the ankles, his knees being flexed over the doctor's shoulders, with head and arms dangling toward to floor. In that position he subjected him to "double-quick motion around the operating-room, and after about three minutes, the sounds of restored respiration were heard." The doctor further states:—"Each step was taken with a springy motion, by which the weight of the intestines resting upon the diaphragm would be alternately applied and removed with the tread, the effect of which would be calculated to stimulate the heart and force the blood along its channels, while the air was simultaneously changed in the lungs." Three other cases are related, one a young woman of great weight (140 lb.), another a physician, who were subjected to similar treatment with alike favorable results. As it appears that in

two of the four cases reported, the Marshall Hall method of restoring animation was had recourse to, without success, before adopting the method described, the success of the new method appears to be the more remarkable, seeing a considerable time (not noted) was said to have elapsed before it was commenced. That fact caused me to hesitate in crediting the report, but the circumstantiality in detail, the names and dates, etc., forbade my entertaining any doubt of its genuineness.

From the preceding remarks, it will be apparent, that, in my opinion, chloroform is the best anæsthetic yet discovered; that it is quite safe if judiciously administered, and its action closely watched; that the pulse, and not the respiration, gives the first indication of danger, and ought, therefore, not only to be constantly under the fingers, but to occupy the attention. —*Australian Med. Jour.*

APPENDICITIS:—MEDICAL AND SURGICAL MANAGEMENT.

At the September meeting of the Missouri Valley Medical Society, Dr. A. F. Jonas, read a most interesting paper on the above subject. Notwithstanding the fact that the topic is almost worn threadbare, it is one of such importance that the physician should be alive to the necessity of being ever ready to meet it, especially does this apply to those physicians practicing in rural districts where they do not have time nor opportunity to call counsel.

While surgery is making such rapid strides followed by most brilliant results; he advises the younger practitioners not to be carried away with the idea that medicinal means are of no avail, in the tieatment of appendicitis, but urges a more thorough study of the disease, and accuracy in diagnosis. Good sound judgment and anatomical knowledge of the parts are absolutely necessary, before the physician can be sure of just when to call surgery to his aid.

He gives a table of a series of thirty cases, which have occurred in his practice, or have come under his notice. The treatment was largely surgical; a few cases apparently recovered under medicinal measures. After carefully considering the various means, usually employed in the treatment of appendicitis he summarizes as follows:

1. When called early, insist on absolute rest in bed.

2. Fomentations, if pain is severe, and give codeine if necessary.

3. Salines (liberal doses) every half hour until four to six fluid stools are produced.

4. If the salines, after having produced free catharsis, fail to relieve, or aggravate the pain and fever; *operate.*

5. If salines fail to produce free catharsis; *operate.*

6. Temporizing with salines, or any other form of medicinal treatment, is worse than useless. When there is the slightest evidence of the presence of pus, an operation must be done at the earliest possible moment.

7. Guard against over-zealousness in search of the appendix, in large abscess cavities, lest the limiting intestinal agglutination be broken down and general peritoneal infection follows.

8. Always remove the appendix when it can be safely done.

9. Elevate the pelvis, as in Trendelenburg's position, in cases of small abscess limited to the lumen of the appendix or its mesenterium, or in any case when the peritoneal cavity is entered and where the intestinal distention is such as to make it difficult to find the caput-coli, or the appendix.

WHY SHOULD I NOT USE THE FORCEPS?

This is the title of a highly interesting paper, read before the Topeka Medical Society, by Dr. M. R. Mitchell.

After giving a brief history of the forceps, mentioning the principal objections to their use as well as the advantages, he concludes that three questions present themselves, viz.: "How can they be suc-

cessfully and advantageously used ?"

"When should they be used ?"

"Why should they be used ?"

In answer to the first query, he says the main points are accurate diagnosis; thorough knowledge of the mechanism of labor; perfect cleanliness; gentleness and a cool steady hand. Every physician should possess reliable instruments and accustom himself to their use.

The indication for their employment is a matter of judgment, and the individual case.

Before resorting to the forceps the accoucheuer should have ready all necessary medicine and appliances, in case of danger to the child, or hemorrhage following. Coolness and decision should characterize his movements under all circumstances. He thinks that those who condemn their use and portray tales of woe and bloody work of the instrument, have entirely misjudged their proper and judicious use; that where properly and skillfully applied they do not cause laceration of the perineum that would occur in normal labor.

He declares that many mothers' lives might have been saved; and there would be fewer still-born children if physicians did not so closely adhere to that adage, "Meddlesome mid-wifery is always mischevious."

A CASE OF ALBUMINURIA DURING PREGNANCY.

In a paper read before the Obstetrical Society of Cincinnati, (*Med. Progress*), Dr. C. D. Palmer gave the history of a case of a patient who he found had considerable swelling of face and albuminous urine.

Fearing puerperal convulsions, he placed her on saline treatment and then deemed it best to induce labor.

Improvement began, and the albumen diminished. On fourth day after delivery, however, she began to have difficulty of breathing. On examination he found that she had a commencing pneumonia. She was placed under the influence of carbonate of ammonia and small doses of morphia. Next day finding an irregular dicrotic pulse of 140 to 150, he gave her hypodermically two drops of a one per cent. solution of nitro-glycerine.

Immediate improvement followed, this dose was repeated three times daily, for a while and then given by the mouth.

The urine became less albuminous and breathing less laborious; at the end of a month the patient was discharged.

While nitro-glycerine has no direct action on the heart, it has a most potent influence, indirectly. It will increase the secretion of urine by directing the blood from the kidneys, in Brights' disease, to the outside of the body.

This is the third case of this kind, in which Dr. Palmer has used nitro-glycerine with the same pleasing results.

PLACENTA PRAEVIA.

Dr. R. S. Kelso read a very interesting and practical paper before the South-west Medical Society at West Plains, Mo., (*Kansas City, Med., Index*) on the above subject. He prefaces his article, by giving the history, symptoms and pathology of the trouble, and urges more thorough study and preparation to meet the emergency.

The treatment varies: the general rule holds good, that what is best for the mother, is best for the child, i. e., speedy delivery.

Slight hemorrhages, require nothing further than close watching and rest in bed.

When hemmorrhage is severe, or oft repeated, delivery should be hastened.

If the os is but slightly dilated, tampons may be used,—being left in for twenty-four to thirty-six hours. Then on removal if dilatation has occurred sufficiently, grasp the presenting part or turn and deliver. Strict antisepsis should always be observed.

The situation is one of such gravity that the physician should not loose his head. A steady nerve and knowledge of what to do at the right time, will help him in many trying moments.

Veratrune Viride in Scarlet Fever.

In the *Columbus Medical Journal* Dr. R. E. Chambers gives his practical experience of over thirty years, in the use of this remedy. He claims that it has always given him good results, and that when called to a case of scarlet fever, he has a remedy that will not disappoint him in cases free from such complications as failure of the kidneys to secrete, pulmonary edema, etc. Furthermore, these complications will not occur if the case is seen and treatment begun early. As proof of the usefulness of the drug in this disease, he cites an instance in which he was called to a family of eight children, all ill with a severe type of scarlet fever,—circulation rapid, fever high, throats intensely swollen and offensive. Giving a most unfavorable prognosis, he began giving Norwood's tincture of veratrum viride with nitric ether; using one drop of the veratrum for each year of age of child, with three times the amount of ether. This medication was continued every hour, until vomiting was produced; then discontinued until fever should be manifest, then every three hours until vomiting should occur again. A solution of Chlorate of Potash was used in their throats, also free sponging externally. This treatment was followed out and in a few days the cases were convalescent.

He considers the drug a safe and sure remedy in the treatment of scarlet fever even claiming that some cases be aborted by its timely use.

Specific Urethritis in Children.

Dr. John A. Weyeth, in a clinical lecture, said that gonorrhœa in young children is comparatively rare. Reference to works on diseases of children fail to show anything on this subject, and standard authorities on genito-urinary diseases mention but few isolated cases.

He is of the opinion that there are many cases that escape observation, or are treated for something else.

The principles of treatment do not differ from those which govern specific urethritis in an adult. The principle interest centres in the diagnosis, which must be accurately made in every suspicious case.

Emergencies.

Accidents in giving Anæsthetics.—Tincture of digitalis hypodermically; draw out the tongue and see that respiration is not mechanically impeded; invert the patient quickly and temporarily; use forced respiration promptly; apply external warmth and stimulation; avoid the exhibition of alcohol.

Angina Pectoris.—Inhalation of chloroform, or a few drops of nitrate of amyl; 1-100 grain of nitro glycerine, internally; placing the feet in hot water; mustard to the precordial region; dry cup between the shoulders; hypodermic injections of morphine and atropine; administration of stimulants and anodynes.

Apoplexy.—Elevate the head and shoulders; if pulse is moderately strong and the brain congested, bleed from the arm freely, sixteen ounces or more; electerine (one-sixth grain) or croton oil, two drops in a drachm of sweet oil or glycerine; cold to the head by means of an ice bag.

Asphyxia—In drowning, hold the patient's head downward for a few seconds. In hanging or choking, bleed from the jugular. If there is obstruction to passage of air through the mouth or nose, open trachea. Artificial respiration at once, and to be continued. Friction, warmth, warm bath (100°) ammonia to nostrils, galvanizing of phrenic nerve.

Asthma, Spasmodic.—Hypodermic of atropine into the nape of the neck; inhalation of smoke of stramonium leaves; fluid extract of nux vomica, internally, alcohol, ether, chloral, opium; inhalation of chloroform cautiously administered.

Colic, Gall.—Morphine, hypodermically; inhalation of chloroform; hot applications to the abdomen.

Coma.—Dark room; head high and cool; head shaved; low diet; croton oil; if due to compression, antiseptic trephining; if due to anæmia, pilocarpine and hot baths.

Heat Stroke.—Remove clothing, sprinkle with water, cold cloths to the head, hot cloths to the feet; antipyrin; bleeding in robust subjects. After temperature is reduced give alcohol and diffusible stimulants, hypodermically if necessary.

Hiccough.—Acid drinks, cold douches, ether or chloroform internally, externally or by inhalation; musk, opium, antispasmodics.

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF OBSTETRICS

For January contains two articles on

Ectopic Gestation.

The paper by Dr. James W. Ross, of Toronto, Canada, is a scholarly article, well worth the attention of the practitioner, whether he be an abdominal surgeon or no. In his classification of the different varieties of this accident, Dr. Ross follows Tait and Parry closely. He thinks that ovarian pregnancies are as yet not proven and, while stranger things have happened, the proofs adduced do not seem to him convincing. Of the causes of extra-uterine fœtation, he considers gonorrhœa the most frequent; acting, as it does, by destroying the cilliated epithelium of the tube and preventing the passage of the ovum into the uterus. The symptoms are minutely discussed and stress is laid on a period of sterility followed by a supposed abortion. Should such a patient present herself with a pelvic mass and elevated temperature, she should be closely questioned as to the supposed abortion, as such, he says, are frequently cases of ruptured ectopic gestation. As to the diagnosis of extra-uterine pregnancy before rupture, he says, "no man can be positive of his diagnosis of intrapelvic disease until it is confirmed by abdominal operation." The assertion is a sweeping one, yet we believe it to be true in the main. In regard to the treatment, he thinks that there is but one—the knife. Of electricity, he remarks that there is, as the Yankee said, "nothing to it." The argument for and against electricity is discussed in the same masterly manner that characterizes the whole paper. The article closes with a table of extra-uterine operations.

The second paper on "Extra-uterine Gestation,"* from the pen of Dr. Edwin B. Cragin, of New York, deals with the subject purely from the operative point of view and is an account of the operations the author has performed, with the history of the cases. The article is illustrated with several photographs of the specimens. In his views on the diagnosis and treatment, he coincides with Dr. Ross.

Dr. W. W. Jaggard, Chicago, contributes a

Note on one of the Conditions of the Use of Electricity in the Treatment of Uterine Fibroids.

Electricity was applied in a case of multiple fibromata, in accordance with Apostoli's method, with the result that the tumor became perceptibly harder and the oozing of blood ceased. After two or three applications the patient developed a fatal septic peritonitis and at the post-mortem the peritoneal cavity contained serum, flakes of lymph, and two tablespoonfuls of pus. The tubes presented signs of catarrhal salpingitis, but contained no pus. The case goes on record as a death following the use of electricity for fibroids; whether the fatal result was due to the agent used or not. Again, it confirms the observation often made that disease of the adnexa is present in nine out of ten fibroids, as shown in those removed by hysterectomy. Since Apostoli has pointed out that tubal disease is a contra-indication to the use of electricity, it would seem as if the number of fibromata suited to his treatment is very limited.

Ventral Hernia Following Laparotomy

Is the title of a paper by Dr. L. H. Dunning, of Indianapolis. The various causes of this accident are well shown, such as the prolonged use of the drainage tube, constipation, and a lack of tonicity of the tissues. The prevention of the trouble lies in the careful approximation of the divided structures, with avoidance of the other conditions that lead to hernia. The abdominal binder is recommended to be worn for at least a year after operation. The operations for the relief of the hernia are clearly described.

Dr. Samuel L. Weber, of Chicago, contributes

A Prompt and Radical Cure of Mammary Abscess by a New Method of After Treatment.

He treats the abscess by an incision in a line radiating towards the nipple and a thorough curetting of the abscess cavity, followed by a douche to wash out all debris. The cavity is then packed with strips of gauze soaked in a one per cent. carbolic solution; the packing being renewed every twenty-four hours. After two or three days of such packing the cavity will be found healthy and filling up with granulations. The packing is now stopped and the wound covered with a thin layer of gauze over which a large flat sponge is placed, covered with a piece of oiled silk, and held in place by a firm bandage; the idea being to make as firm compression as possible. To aid in this compression, the sponge is soaked, after the bandage is in place, with the carbolic solution. The breast should be compressed flat against the chest and not in the pendant position. The author claims that, by this method, the duration of treatment is very much shortened. The new part of the treatment claimed consists in the firm compression. Neither principle nor method are new.

Dr. J. G. Clark, of Baltimore, reports a "Cystoma Ovarii Glandulare Associated with Hydrops Polliculi." The article is illustrated with three cuts of the tumor, which was removed at the Johns Hoskins Hospital.

Dr. W. D. Porter contributes a paper on the

Management of the Third Stage of Labor.

His plan is a slight modification of the well know Crede method. As soon as the child is born the uterus is grasped with both hands, but no compression is made until one or two pains have occurred. With each pain compression is made, but not with enough force to make the woman complain. When the placenta is felt to have slipped into the vagina an antiseptic finger is passed into the vagina and hooked into the placenta, pulling it

* "Operative Experience with Ectopic Gestation."

gently out, while the other hand makes pressure on the uterus from above. The procedure would seem to have no special advantage over the older method.

Dr. W. W. Jaggard reports a case of "Thorapagus." The monster was composed of two relatively equal female forms, disposed face to face, and confluent at the anterior aspect of the thorax and abdomen. Labor lasted about eight hours, one and one-half hours being consumed in the extraction which required considerable force. Patient recovered.

Dr. S. Marx, of New York, reports a "Case of Accidental Hemorrhage During Labor." Dr. Mary Almira Smith reports a successful case of "Porro-Cæsarean Section," which was performed for a deformed pelvis, rendering natural birth impossible.

This number concludes with a memorial notice of the late Professor A. Reeves Jackson.

THE THERAPEUTIC GAZETTE.

The two more important articles of the December issue of the *Therapeutic Gazette* are "The Surgical Treatment of Appendicitis and its Limits" by Dr. W. E. Ashton and "The Medical Treatment of Appendicitis and its Limitations" by Dr. James Graham. These two articles were the subject for discussion at the Clinical Meeting of the Alumni of the Jefferson Medical College. Dr. Stark offers a paper, "The Creasote Treatment of Tuberculosis." These observations are based on a personal analysis of numerous cases. Dr. Kelly's "Treatment of Pneumonitis with Digitalis" will be read with some interest.

THE PRACTITIONER.

The Practitioner comes to us for December with three articles. The most important of these is "The Dietetic and Medicinal Treatment of Rheumatoid Arthritis" by Dr. John K. Spender.

THE GLASGOW MEDICAL JOURNAL.

Dr. Buchanan's paper,

A Case of Puerperal Fever, illustrating the Mode of Infection and the Infective Agent,

says, in discussing the source of the infective agent, that there is a deep-rooted belief that this is conveyed in most cases to the patient; and no doubt it is very often transmitted from other cases of puerperal fever, but it is probable that in a considerable number of cases the patient herself is the source of the infection. For the streptococcus pyogenes, which is always present in these cases, may be cultivated from mucuous surfaces apparently healthy. He, therefore, believes that this microbe is present in the vagina before labor. It may be introduced into the uterus before or after labor. Moreover, he further states, there is a *possibility* of infection from an "old unilateral salpingitis." Mr. John McGregor's article "The Epidemic of Cholera in Paris" and three small papers read before the *Glasgow Pathological Society* complete the December issue.

EDINBURGH MEDICAL JOURNAL.

In December's number Mr. Milton offers a "few words" about the pathology and treatment of "Lupus"—before the tale is told quite a lengthy article appears. Dr. A. G. Miller's paper,

Excision or Arthrectomy of the Knee Joint,

states that by the terms excision and arthrectomy is meant that operation, exclusive of amputation, by which all the diseased tissues are removed, with the best possible results to the patient in the shape of a useful limb. He says that experience has taught him that, to get a satisfactory result in strumous joints, it is necessary to remove the whole of the diseased synovial membrane. His method in operating is, after reflecting a semilunar flap of skin well above the patella, to cut through the tendon of the extensor of the thigh a little above the patella, and also through the fibres of the vasti, internal and external. In this way the synovial membrane is exposed. It is then easy to push up the muscular substance, draw down the thickened synovial membrane, which comes off the periosteum readily, and then to cut at its attachment round the articular surface of the femur. In this way four-fifths, or thereabouts, of the synovial membrane is removed in one mass with the patella imbedded in it. Those portions of the membrane that cover the ligaments are then removed by the use of the Lister sharp spoon. The ligaments should be scraped till they appear clean and white. They are then cut through to permit of complete flexion of the joint, and the operation is completed by the removal of a sufficient amount of bone. There seems to be one fact further to consider in the review of this paper, and that is, the removal of the patella, which, he states, is not an object of his operation, but is a necessary part, for it comes away in the centre of the synovial mass. He does not consider the removal of the patella a disadvantage; because (1), it is often diseased; and, (2), if the resulting limb be thoroughly anchylosed and rigid the function of the patella is gone, and the straight limb looks neater without it.

"Some Practical Results of the Investigation of Cholera in Germany," by Dr William Russell completes the list of communications of any merit.

THE DUBLIN JOURNAL OF MEDICAL SCIENCE.

Of the five papers offered in the December number possibly the most important one is an address by Dr Hamilton, President of the Section on Surgery in the Royal Academy of Medicine in Ireland, on "The Surgery of To-day." He gives an exceedingly interesting and instructive account of the growth of surgery from the time when bleeders, cuppers, and leechers were in vogue to the placing of surgery on a tripod of three solid and enduring feet—anæsthetics, antiseptics and experimental research.

SELECTED FORMULÆ.

Emulsion Castor Oil.

℞ Castor oil..... 1 oz.
Syrup rhubarb..... 4 drachms.
Alcohol..... 4 drachms.
Essence peppermint..... 2 drops.

Mix, and shake well together. The taste of the oil is completely disguised.

—*Phar. Era.*

Liniment for Neuralgia.

℞ Chloroform..... ʒvi.
Sulphuric ether..... ʒi.
Spirits camphor..... ʒiii.
Tinct. opium..... ʒiss.

M. Sig.—Soak a small piece of flannel with the liniment, and apply over the painful part.

—*The Doctor.*

To Clean Cistern Water.

Add two ounces of powdered alum and two ounces of borax to a twenty-barrel cistern of rain water that is blackened or oily, and in a few hours the sediment will settle, and the water will be clarified and fit for washing.

—*Tex. Health Jour.*

Serous Diarrhœa.

℞ Pulv. opii..... gr. i.
Plumbi acetat..... gr. ii.
Camphoræ..... gr. i.

M. ft. Pil. no. 1.

—*H. A. Hare.*

For Removing Warts.

A most successful means of removing the ordinary wart, whether situated on the hands or elsewhere, is as follows:

℞ Acid salicylici..... g. xxx.
Ungt. aquæ rosæ..... ʒ ss.

M. S. Apply twice daily for two days, after which the growths being softened, they should be removed by a dermal curette, and by using these means you can safely say that the wart will not return.

—*J. Abbott Cantrell.*

For Small Hemorrhoids and Pruritus Ani.

℞ Hydrarg. chlo. mitis..... gr. xx.
Cocaine muriat..... gr. x.
Petrolati..... ʒi

M. ft. ung.
Sig. Apply as directed.

An Ointment for Hemorrhoids.

℞ Hydrochlorate of cocaine..... gr. xviii.
Sulphate of morphine..... gr. iv.
Sulphate of atrophine..... gr. iv.
Tannic acid..... gr. xviii.
Vaseline..... ʒi.

This ointment is to be applied to the hemorrhoids.

—*L' Union Med.*

Tape Worm.

Treatment.—Fast patient eighteen hours, and purge during the time. Then give hourly, wineglass doses of pomegranate decoction, made as follows:

℞ Fresh Pomegranate Bark..... 2 ounces.
Aquæ Puræ..... 2 pints.

Boil down to one pint, strain and use.

It is necessary to get the head in order to establish a permanent cure.

—*The Doctor.*

For Frost Bite.

℞ Ol. lavandulæ
Acid. carbolic..... āā fʒss.
Olei oliv..... fʒy.
Unguent. plumbi
Lanoliui..... āa ʒx. M.

Ft. ung. Sig.—Apply topically.

—*Lassar, Med. News.*

Habitual Constipation.

℞ Extract physostigmatis
Extract belladonnæ
Extract nucis vomical..... āā gr. ¼.
Aloin..... gr. ½.

M. ft. Pil.

—*Prof. R. Bartholow.*

Coccydynia.

Whitla recommends the following suppository employed at bed-time.

℞ Ext. belladonnæ..... ¼ grain.
Ext. hyoscyami..... ¾ grain.
Iodoform..... ¼ grain.
Ol. theobromæ..... 20 grains.

Nervous Cough.

℞ Acidi Hydrocyanic Dil..... 1 drachm.
Tinct. Sanguinariae..... ½ ounce.
Syr. Senegae..... 4 drachms.
Aquae Lauro-cerasi..... 7 drachms.
Spr. Tolu..... 2 ounces.

M. Sig. From ten drops to a teaspoonful every four hours, according to the age of the patient.

—*The Doctor.*

Painless Dilatation of the Cervix Uteri.

For this purpose, Le Fort recommends:

℞ Iodoform..... ʒiii.
Powdered cocaine..... gr. lxxx.
Sulphuric ether..... ʒiii.

Make a solution, and wet a laminaria tent with the same. This may then be introduced into the uterine canal, and dilatation obtained without causing pain.

—*L' Union Med.*

Detection of Pus in the Urine.

Drop into the specimen of urine enough tincture of guaiac to give it a milky appearance, and heat it a few minutes to 100°F. If pus is present a blue tint will develop. Otherwise, the urine may be passed through a white filter, on which is then allowed to fall a few drops of tincture of guaiac, producing, if pus is present, a distinct blue discoloration.

—*Ex.*

Treatment of Gonorrhœa.

Dr. W. J. James, of Cleveland, Ohio, has employed the following injection with excellent results in the treatment of a case of chronic gonorrhœa, where solutions of sulphate of zinc, nitrate of silver and bichloride of mercury proved inefficient, and he has derived equal benefit from it in acute cases.

℞ Boracic acid..... ʒiss.
Tincture of iodine..... ʒii.
Glycerine..... ʒi.
Distilled water q. s. ad..... ʒiv.

M. Sig. To be used as an injection every morning and night.

He would like other physicians to give this formula a trial.—*Med Bull.*

Solution for the Treatment of Chancre.

DU CASTEL is stated to use the following solution in the treatment of chancre, by *L'Union Medicale.*

℞ Carbolic acid..... gr. xv.
Alcohol (90 per cent.)..... ʒiiss.

Make a solution, and with a small pledget of cotton or wool touch the surface of the chancre. A light touch is generally sufficient. Cicatrization usually readily ensues.

—*Ther. Gaz.*

Catarrh, Acute Nasal, with profuse watery Secretion.

℞ Tinct. Aconiti Radicis
Tinct. Belladonae..... āā ʒij.
Tinct. Apii deodoratae..... ʒ iv.

M. Sig.—10 to 12 drops in water every three or four hours.

—*W. H. Bricker.*

For Asthma.

Bartholow recommends:—

℞ Potassii iodide..... ʒ iij.
Ext. belladonnae fluid..... f ʒ j.
Ext. lobeliae fluid..... f ʒ ij.
Ext. grindeliae fluid..... f ʒ ss.
Glycerini..... f ʒ iij. M.

SIG.—A teaspoonful as required.

Transfusion Fluids.

The following are given in the *Prescription:*

1. Billroth's.

℞ Sodium phosphate..... gr.iij.
Sodium carbonate
Ammonium carbonate.....āā ℈j.
Sodium chloride..... ʒj.
Alcohol..... mclx.
Dist. water..... q. s. ad ʒxx.

M.

2. Little's.

℞ Sodium phosphate..... gr.iij.
Potassium chloride..... gr. vj.
Sodium carbonate..... ℈ij.
Sodium chloride..... ʒj.
Dist. water.....q. s. ad ʒxx.

M.

3 Walter's.

℞ Sodium bicarbonate
Calcium chloride
Potassium chloride.....āā gr. vj.
Sodium chloride..... ʒj.
Distilled water.....q. s. ad ʒviij.

M.

For use, dilute 1 fl. oz. of this solution with water at 120°F., so as to make 16 fld. oz.

Dr. Stark, *Therapeutic Gazette*, in concluding his paper on "The Creasote Treatment of Tuberculosis," submits the following *resume:*

First.—Creasote is no longer an innovation or a fad, but a drug which has come to stay as an antitubercular remedy.

Second.—Creasote is particularly valuable in the earlier stages of tuberculosis.

Third.—Its administration must be in moderate doses for a prolonged period.

Fourth.—That it is a safe and reliable prophylactic in the condition that is usually described as pretubercular anæmia.

Fifth.—It should be administered in combination with approved adjuvant remedies.

There are several easy and palatable methods of administration. The following prescriptions are ordinarily employed by me, the daily doses being dissolved in some alcoholic or vinous mixture, as whiskey or sherry wine.

℞ Creosoti (beechwood)..... mxlv.
Glycerini..... ʒi.
Aquæ destil..... ad ʒii.
Dose.— ʒi t. i. d.

℞ Creosoti (beechwood)..... ʒi.
Tinct. gentian comp..... ʒii.
Dose.— mxv t. i. d.

℞ Creosoti (beechwood)..... ʒss;
Bismuthi subnitrat..... ʒi.
M. et f. in capsul. no. xv.
Dose.—One every four hours.

"Which side should I sleep on, doctor?" he inquired. "In winter or summer?" asked the doctor, rubbing his chin thoughtfully. "What's that got to do with it?" exclaimed the patient, half angrily. "A great deal," responded the doctor, mysteriously. "I don't see it." "Of course you don't," said the imperturbable; "if you did you wouldn't be here asking me questions about it." "Go ahead, then," said the patient, sitting back resignedly. "Well," continued the doctor, "in winter, when it is cold, you should sleep on the inside; but in such weather as this you should sleep on the outside, in a hammock with a draught all round it, and a piece of ice for a pillow. Two dollars, please."—*Med. Record.*

Man, born of woman, is of few days and no teeth. And indeed it would be money in his pocket sometimes if he had less of either. As for his days, he wasteth one-third of them. And as for his teeth, he has convulsions when he cuts them. And as the last one comes through, lo! the dentist is twirling the first one out; and the last end of that man's jaw is worse than the first, being full of porcelain and a roof-plate built to hold blackberry seeds. —*Burdette.*

Polite Doctor (cautiously)—"Your husband is suffering from overwork or excessive indulgence in alcoholic stimulants —it is, ahem! a little difficult to tell which."

Anxious wife—"Oh, its overwork! Why, he can't even go to the theatre without rushing out half a dozen times to see his business partners."—*Judge.*

PERISCOPE.

MEDICINE.

Tendon Reflexes.

The following classification of tendon reflexes by Dr. William C. Krauss (Buffalo Med. and Surg. Jour.) will be found useful:

Exaggeration of Tendon Reflexes.	Organic Disease.	Spinal Cord.	1. Myelitis 2. Amyotrophic lateral sclerosis. 3. Paraplegia spastica. 4. Multiple sclerosis. 5. Syringomyelia and hydromyelia. 6. Hematomyelia and hematorrhacis. 7. Spinal tumors. 8. Pachymeningitis hemorrhagica interna. 9. Pachymeningitis cervicalis hypertrophica. 10. Brown-Sequard's spinal paralysis. 11. Arthritic muscular atrophies.
		Brain.	1 Hemiplegia. { Cerebral apoplexy. / Cerebral embolism / thrombosis. / Acute encephalitis 2. Hematoma. 3. Hydrocephalus 4. Senile dementia.
	Functional Disease.		1. Hysteria. 2. Epilepsy. 3. Neurasthenia. 4. Paramyoclonus. 5. Tetanus. 6. Psychoses. 7. Infectious processes.

Abolition of Tendon Reflexes.	1. Neuritis. 2. Looomotor ataxia. 3. Poliomyelitis anterior. 4. Spinal muscular atrophies. 5. Hereditary ataxia (Friedreich.) 6. Chorea molle. 7. Chronic ergotism. 8. Diabetes mellitus. 9. Traumatism.	Simple. Toxic. Endemic. Infective.
Abolition and Exaggeration.	1. Meningitis. 2. Hementia paralytica. 3. Idiocy.	Spinal. Cerebral.

Congenital Syphilis.

Erlenmeyer (*Zeitschrift f. klin. Medicin*, xxi, 3 u. 4, p. 343) has reported seven interesting cases of congenital syphilis which he has studied in their relations to certain diseases of the nervous system. He expresses the view that late forms of congenital syphilis, so-called syphilis hereditaria tardia, may appear later than the twelfth year—that is hereditary syphilis may remain latent more than twelve years. Puberty, traumatism, and febrile affections may afford the necessary stimulation to arouse into activity a latent congenital syphilis. The law of Colles, that the mothers of children congenitally syphilitic through the fathers, is not without its limitations. Mothers that have given birth to congenitally syphilitic children may become syphilitic, though not necessarily. Immunity to syphilis is not identical with infection with syphilis. The law of Kassowitz as to the spontaneous gradual attenuation of the intensity of the syphilitic hereditary transmission is not absolute. Children born late may be infected in more intense degree than those born previously. Hereditary syphilis may alternate with the sexes; thus, if after the birth of a congenitally syphilitic child a non-syphilitic child of different sex is born, it is not proved that the capability of hereditary transmission through the father is exhausted. In arriving at a conclusion all the children must be considered. Anti-syphilitic treatment of the parents exerts a most favorable influence upon subsequent children. A form of cerebral disease development characterized by unilateral convulsions and lack of development is most commonly of syphilitic origin. The so-called cerebral paralysis of children and congenital epilepsy, with or without idiocy, are frequently dependent upon congenital syphilis. —*Med. News.*

Right Hemiplegia and Aphasia Following Diphtheria in a Child.

Allen A. Jones, M. D., Lecturer on Practice of Medicine and Instructor in Practice, Medical Department University of Buffalo, contributes the following to the *Medical News*:

In May, 1891, I attended Florence T., eight years old, during a severe attack of diphtheria. The local and constitutional manifestations of the disease were pronounced, but the patient passed safely through the severe stages, and in about ten days was free from pyrexia, had a clean throat and a good pulse. The child seemed so well that I ceased making daily visits. One morning, however, I was hurriedly called, and found her with complete right-sided hemiplegia and ataxic aphasia. The right side of her face was entirely paralyzed. Her mother informed me that the child was talking and laughing an hour before I was summoned.

She was not unconscious at any time. The usual evidences of pharyngeal paralysis existed. No cardiac bruit was detected. The patient's mentality seemed sluggish for a few hours subsequently to the attack, but thereafter was normal.

Her repeated attempts to make herself understood were unavailing, as she produced only inarticulate sounds. Sensation was normal, so far as I was able to elicit. The patellar reflex was very weak and alike on both sides. Headache was not present. No pain was felt in any part of the body. After the lapse of two days, she was able to extend, but not to flex, her leg. Motor power gradually returned, first in the leg and thigh, then in the hand and arm, lastly in the face and pharynx. In about six weeks the little patient was playing out-of-doors, apparently as well as before her illness.

A few days ago I went to see her, and was struck by her frail appearance. She has grown very little, if any. She is very thin. Her eyes are large and her pupils dilated. No areas of anesthesia were found. Her patellar reflexes on both sides were almost imperceptible. Her sister states that the child has always spoken slowly since her illness. Her grandfather states that she has never been the same since, but is weak in body and mind.

Jaborandi in Hiccough.

Nobel and Stiller (*Centralbl. f. Klin. Med.*, 1892, Nos. 32 and 42) respectfully refer to the good effects produced by jaborandi in hiccough. Nobel's patient was a man suffering from influenza, and the infusion of jaborandi was used. Nobel draws attention to the fact that, notwithstanding the presence of some cyanosis, the drug had no ill effect upon the heart. He refers to other recorded cases, and adds that it remains to be proved which constituent in jaborandi brings about the good results. Stiller says that he has long used pilocarpine (10 drops of a 1-per-cent. solution three or four times a day) in hiccough of nervous origin, and that it is the best remedy known for this condition. He does not employ it in the reflex hiccough of severe abdominal disease and peritonitis. At times, and especially in hysteria, only improvement or temporary cessation in the hiccough has been obtained, necessitating the further use of the drug. Stiller says that the good effects of jaborandi are due to pilocarpine.—*Med. Age.*

Gout in a Child Eleven Years Old.

Marboux (*Lyon Medical*, 1892, No. 43, p. 264) has reported the case of a girl, eleven years old, in which, after a brief period of malaise, sore-throat, and difficulty in swallowing, pain, redness and swelling appeared at the metatarso-phalangeal joint of the right great toe. On the following day, the symptoms subsided with the abruptness with which they had appeared, some discoloration, pain, and swelling, however, persisting. A day later, the great toe of the left foot became similarly involved. Forty-five grains of sodium salicylate were administered in twenty-four hours, and decided improvement followed. There was no doubt from the mode of onset, from the appearance of the affected parts, and from the progress of the case, that the condition was gout. There was no family history of gout on either the father's or on the mother's side. The father had, however, eighteen months previously, had an attack of the same kind as the child. The child did not suffer from migraine or from gastric disorder or from cutaneous eruptions, nor had menstruation occurred.—*Med. News.*

Expectant Treatment in Typhoid Fever.

Dr. Arnot Spence details the results from this plan in three hnndred and twenty-three cases of typhoid fever (*Med. Rec*). Upon terminating his article he says: In conclusion we can say that of our cases nearly four per cent. died as the result of admission in a moribund state; that over three per cent. died of the accidents incidental to the intestinal lesions, as hemorrhages, perforation, and peritonitis; that 1.5 per cent. died of complicating pneumonia; that 6.8 per cent. died of the typhoid poison itself and its resulting exhaustion. That the death-rate was higher among the females than the males, and that the lowest mortality was in those cases of an age between fifteen and twenty years.

It is not likely that any treatment can be devised which will prevent absolutely such occurrences as intestinal hemorrhages and intestinal perforations, and therefore we shall have those to contend against. A treatment which may possibly antidote the specific poison of typhoid fever without lowering the vitality of the patient will be, in accordance with our present theory, the one to reduce its mortality.—*Wkly. Med. Rev.*

Treatment of Morphinism.

Obersteiner individualizes strictly in the treatment of the morphine habit. Beginning with the average daily dose, he withdraws it as rapidly as the patient can stand it. When the dose has been reduced to a few centigrammes, caution is necessary, as even a slight reduction is then badly borne. At this stage warm baths of from 5 to 15 minutes' duration, followed if necessary by the cold shower or cold pack for one-half hour to two hours at a temperature of 78° to 86° F., are often of benefit. Alcohol in liberal quantities often gives relief. Cocaine has no other use than to modify the symptoms, and should only be used when these become violent, say twenty-four to forty-eight hours after the last dose of morphine; it is always given by mouth in doses of 0.05 to 0.1 gramme, never exceeding 0.5 gramme per day, it should be reduced in a few days, and never continued longer than five or six days. Nutrition must

be improved by all possible means. If collapse occurs, morphine must be resorted to. Patients with cardiac troubles should not be subjected to complete withdrawal.—*Wien. Med. Presse.*

SURGERY.

Radical Cure of Femoral Hernia.

Salzer describes a new method of radical cure of a large femoral herniæ. He objects to any attempt to bring together the margins of the ring by sutures, as the resistance of the fibrous structures would very probably cause local gangrene and sloughing. The plan of closing the canal by cicatrical tissue, either by removing its fatty and glandular contents, or by inserting foreign material, is also open to objection, as the new tissue thus produced is apt to become absorbed. His method consists in first removing the sac, and in the next place, in closing the external orifice by a flap formed by the fascia covering the pectineus muscle. This flap, the free convex margin of which is divided downwards, whilst its upper portion remains attached to the muscle, is turned upwards and fixed by sutures to the middle third of Poupart's ligament. In this way the septum crurale is replaced by a tough and resistant layer of fibrous tissue. The thickness of the pectineal fascia, it is stated, varies in different subjects, but the membrane is most likely to be found sufficiently resistent in old persons, and in those who have for a long time worn a truss for femoral hernia.—*Brit. Med. Jour.*

Significance of the Subjective Cerebral Symptoms in Middle-Ear Inflammation.

Dr. H. Knapp (*Archives of Otology*) says:

1. *Transient headache, nausea, vomiting,* and *dizziness,* in acute cases, indicate meningitic irritation. These cases almost all recover with or without mastotomy, only a few exceptional cases of fatal termination being on record.

2. *Persistent headache, nausea, vomiting,* and *dizziness* especially when the discharge from the ear diminishes, signify transition of meningitic irritation into real meningitis, and demand surgical interference—paracentesis of the drum membrane, especially the membrana flaccida when bulging, or opening of the mastoid after Schwartze or Kuster.

3. The *above symptoms* with *delirium, stupor, impediment of speech, chills, spasms, drowsiness,* and *coma* signify fully developed intracranial suppuration. In the majority of such cases it may be difficult or impossible to discriminate between thrombo-phlebitis, extradural and cerebral or cerebellar abscess. The special diagnosis and localization, when strengthened by valuable objective symptoms, such as painful swelling and hardness of the internal jugular vein (sinus thrombosis), localized pain spontaneous or on percussion of the skull (abscess), a fistula in the cranial bones (extradural suppuration), may justify, even demand, surgical interference, namely, opening the posterior cranial fossa to ligate and cleanse the lateral sinus, or opening the posterior or middle fossa to liberate the extradural accumulation of pus, or opening the middle or posterior fossa to evacuate an encephalic abscess. Of all these varieties a certain, though small number of cases (seventeen) is known in which the diagnosis was correctly made and the operation successfully performed.—*Am. Lan.*

Clinical Classification of Hip-Disease.

In a consideration of coxitis Dr. Robert W. Lovett divides the trouble clinically (*Boston Med. and Surg. Jour.*) into four types. These four types are:

1. The Destructive Form, where the disease is rapid, severe, but little influenced by ordinary treatment; extensive infiltration of the soft parts takes place, and in most instances the disease passes on to a fatal issue.

2. The Painful Form, where pain is a prominent symptom, and exacerbations are common.

3. The Quiet or Painless Form, where pain is an unimportant factor or is entirely absent.

4. The Transient or Ephemeral Form, where the symptoms are mild and the course of the disease is run in a few months.

1. The Destructive Form—The type of hip-disease which he would place in this class occurs most often in children of tuberculous inheritance and poor vitality. Its onset is rapid and painful, often excessively painful. There is, almost from the first, much thickening of the trochanter and peri-articular tissues. The general condition is rapily impaired, and abscess formation takes place early. One abscess follows another with profuse discharge through sinuses which open widely and are surrounded by colorless granulations. This type of disease most often begins as such, and is clearly a type by itself throughout. At other times, but rarely, it is superadded to one of the forms about to be described. The temperature is high, the wasting rapid, and a porky induration of the thigh ensues.—*Med. Rev.*

Treatment of Appendicitis.

1. All cases of catarrhal and ulcerative appendicitis should be treated by laparotomy and excision of the appendix as soon as the lesion can be recognized.

2. Excisions of the appendix in cases of simple, uncomplicated appendicitis is one of the easiest and safest of all intra-abdominal operation.

3. Excisions of the appendix in cases of appendicitis before perforation has occurred, is both a curative and prophylactic measure.

4. The most constant and reliable symptoms indicating the existence of appendicitis are recurring pains and circumscribed tenderness in the region of the appendix.

5. All operations should be done through a straight incision; parallel to and directly over the cæcum.

6. The stump after excision of the appendix should be carefully disinfected, iodoformized and covered with peritoneum by suturing the serous surface of the cæcum on each side over it with a number of Lambert stitches.

7. The abdominal incision should be closed by two rows of sutures, the first embracing the peritoneum, and the second the remaining structures of the margins of the wound.

8. Drainage in such cases is unnecessary and should be dispensed with.—*Med. Prog.*

NEWS AND MISCELLANY.

Salipyrin, the sale of which has been interdicted in the United States during the past year, because of conflicting proprietary interests, is now free for use in this country. (December, 1891,) *Notes on New Remedies* published a complete descriptive article on salipyrin. The product has been adopted in medical practice in Europe, and many clinical reports have resulted from trustworthy and authoritative sources. It is expected that physicians in this country will take up the remedy, and that the favorable results obtained by European physicians will be repeated here.

Dr. Mary Putnam Jacobi has been elected as president of the Neurological Section of the New York Academy of Medicine, at its last meeting to succeed Dr. Greame M. Hammond.

Mrs. Jacobi is the first female physician ever elected to the distinguished position of the presidency of a section, in the New York Academy since its foundation; now more than twenty-six years.

This is an honor deservedly bestowed on one who richly merits this unique and distinguished promotion; for though Mrs. Dr. Jacobi is no nerve specialist, her knowledge of diseases of the nervous system is deep and thorough.

It may be said, of this distinguished medical matron, that while progressive and aggressive as a writer, teacher and practitioner of the healing art, she yet preserves to a high degree, those feminine charms and graces so peculiar to the refined and cultured lady.

Dr. Thomas Lyon, the oldest and one of the most prominent physicians in Williamsport, died at his residence, December 25, 1892. His illness was of brief duration, only since the 24th of last month, up to which time he gave earnest attention to his practice as a physician, although he was in the eightieth year of his age.

He was the father of six children, of whom four are living.

The following biography of the venerable physician appears in Meginness' Historical Journal issued in 1888:

"Dr. Thomas Lyon now takes rank as the oldest physician in active practice in Williamsport, Pa. He is a son of Edward Grundy Lyon and Sarah Lyon, of English birth, and was born October 13, 1812, near the borough of Muncy, Lycoming County, Pa. He received his education at the celebrated Milton academy, when the distinguished Rev. Dr. Kirkpatrick was the principal. He studied medicine under the famous Dr. James S. Dougal, of Milton, and graduated at the Jefferson Medical College, Philadelphia, 1838. When he located in Williamsport it had less than one thousand inhabitants, and he has followed his profession without interruption down to the present day. Dr. Lyon has made surgery a specialty, though his practice is general. He is a member of the Williamsport Medical Society, of the Lycoming County Medical Society, of the Pennsylvania State Medical Society and the American Medical Association. He has been president of the city and county associations and vice-president of the State Medical Society. During the war he was a member of the medical board of examiners for army surgeons. His contributions to medical literature have been published in the transactions of the State Medical Society. In 1843 he married Elizabeth R., daughter of Joseph R. Priestly, Esq., of Northumberland, and great-granddaughter of Dr. Joseph Priestly, the eminent chemist and discoverer of oxygen. Dr. Lyon, although in the fiftieth year of active practice, is still hale and vigorous, and gives promise of many more years of service."

ARMY AND NAVY.

FROM JANUARY 8, 1893, TO JANUARY 14, 1893.

The leave of absence granted First Lieutenant Samuel R. Dunlop, Assistant Surgeon, U. S. Army, is still further extended to include January 31, 1893.

The resignation of First Lieutenant Samuel R. Dunlop, Assistant Surgeon, U. S. Army, has been accepted by the President to take effect January 31, 1893.

The order directing Major Robert M. O'Reilly, Surgeon, U. S. Army, to proceed to Washington, D. C., and report for duty as Attending Surgeon, is suspended until further orders.

Lieutenant Col. Charles R. Greenleaf, Deputy Surgeon General, U. S. Army, is de-

tailed as a delegate to the Eleventh International Medical Congress to convene at Rome, Italy, on the 24th of September, 1893, and will, at the proper time, proceed to the place designated. While abroad in pursuance of this order, he will visit such points in Great Britain, France, Germany, Russia, Austria, Italy, and elsewhere as may be deemed necessary by the Surgeon General of the Army, on official business, and on completion of the duty contemplated will return to his station in this city.

First Lieutenant J. D. Glennan, Assistant Surgeon, U. S. Army, having reported at Head-quarters Department of Texas, will proceed to Carrizo, Texas, and report to the commanding officer of the Seventh Cavalry sqadron at that place for duty.

Leave of absence for one month, with permission to apply for an extension of one month, is hereby granted Captain J. S. Powell, Assistant Surgeon, U. S. Army.

First Lieutenant B. S. Ten Eyck, Assistant Surgeon, U. S. Army, having reported for duty at Head-quarters Department of Texas, will proceed to Laredo, Texas, for service in the field, to relieve Captain W. B. Davis, Assistant Surgeon, who, upon being thus relieved, will return to his station, Fort Sain, Houston, Texas.

First Lieutenant Frank R. Keefer, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Riley, Kansas, and will report in person to the commanding officer, Fort Stanton, New Mexico, for duty at that post, relieving Captain John M. Banister, Assistant Surgeon.

Captain Banister, upon being relieved by First Lieutenant Keefer, will report in person to the commanding officer, Fort Leavenworth, Kansas, for duty at that post.

U. S. MARINE HOSPITAL SERVICE FOR THE FOUR WEEKS ENDING JANUARY 7, 1893.

Purviance, George, Surgeon, detailed as chairman of board for physical examination of Passed Assistant Surgeon, S. C. Devan, Dec. 21, 1892.

Gassaway, J. M. Surgeon, to proceed to Gulf Quarantine on special duty, Jan. 4, 1893.

Devan, S. C., Passed Assistant Surgeon, to report for physical examination, Dec. 21, 1892. Detailed for special duty at Philadelphia, Pa., Dec. 28, 1892. Granted leave of absence for two months on surgeon's certificate of disability, Jan. 7, 1893.

Kallock, P. C., Passed Assistant Surgeon, to assume command of the service at Cincinnati, Ohio, when relieved at Boston, Mass., Dec. 21, 1893.

Glennan, A. H., Passed Assistant Surgeon, leave of absence extended sixteen days on account of sickness, Dec. 13, 1892. To proceed to New York, N. Y., for special temporary duty, Jan. 3. 1893.

Williams, L. L., Passed Assistant Surgeon, to proceed to Helena, Arkansas, on special duty, Jan. 3 1893.

McIntosh, W. P., Passed Assistant Surgeon. When relieved to proceed to Boston, Mass., for duty, Dec. 21, 1892.

Magruder, G. M., Passed Assistant Surgeon. When relieved to proceed to San Diego, Cal., on special duty, thence to New Orleans, La., for duty, Dec. 16, 1892.

Cobb, J. O., Passed Assistant Surgeon. When expiration of leave of absence to proceed to Port Townsend, Wash., for duty, Dec. 21, 1892.

Stimpson, W. G., Assistant Surgeon, to proceed to Detroit, Mich., for duty, Dec. 20, 1892.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

MOST POWERFUL BACTERICIDE AND PUS DESTROYOR.

ENDORSED BY THE MEDICAL PROFESSION.

UNIFORM IN STRENGTH, PURITY AND STABILITY.

RETAINS GERMICIDAL POWER ANY LENGTH OF TIME.

USED BY THE HOSPITALS OF THE U. S. ARMY.

Send for free book of 80 pages, giving articles by the following contributors:

DR. P. GIBIER, DR. S. POTTS EAGLETON, DR. C. P. NOBLE, DR. C. A. PHILLIPS, DR. J. H. DeWOLF, DR. J. V. SHOEMAKER, DR. W. S. MULLINS, DR. C. W. AITKIN, DR. H. F. BROWNLEE, DR. J. LEWIS SMITH, DR. J. MOUNT BLEYER, DR. W. B. DEWEES, and many others.

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit, unsafe and worthless to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) is sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border, with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLES ON APPLICATION.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Vaccine Matter.

For the accommodation of our Subscribers, we will supply both Bovine and Humanized Vaccine Virus.

Guaranteed to be fresh and in every respect first-class.

PRICES:

Bovine Crusts,	**$1.50 each.**
Bovine Points or Quills,	**1.00 a dozen.**
Humanized Crusts,	**1.00, small.**
Humanized Crusts,	**2.00, large.**

Nothing less than half dozen sold at these prices.

The Humanized Crusts are warranted to be from typical cases, and in every instance from healthy children, with unquestionable family histories.

Please accompany the Order with the Money.

LOCOMOTOR ATAXIA.

E. H. TOWNSEND, M. D., New Lisbon, Wis.

Locomotor ataxia is a disease due to a lesion of the sensory portion of the spinal cord, associated from its onset with disturbed action of the exodic system. It is a chronic disease, extending over a long period of years (from five to thirty), and is commonly divided into three stages. *First*, invasion; *second*, incoördination; *third*, stages of complications.

I would especially emphasize the fact of its long duration, as a case under my treatment for Bright's disease was diagnosed by a physician, called during my absence, as locomotor ataxia, though the whole duration of the sickness was less than a year. Prof. Erb, of Heidelberg, in Ziemssen's Cyclopædia of Medicine, says: "The duration of the disease is generally very considerable, and is always to be counted by years, and sometimes by decades." Cases may go on to the stage of incoördination in a few weeks; when the symptoms will abate or remain quiet for a long period.

The present name and the impulse to study the conditions of this disease were given by Duchenne, though for years, it had been known as tabes dorsalis.

When fully developed it is characterized by difficulty of walking; disturbed action of the bladder causing slow and difficult micturition; disordered action of the rectum causing constipation, with loss of visceral reflexes; followed, still further in time, by imperfect use of the upper extremities, and by impairment of the visual and auditory senses. Muscular power is not lost, but because of imperfect coördination of the muscles the error of making a diagnosis of paralysis occurs.

The parts of the cord most commonly involved, are the columns of Gall and Burdach, the disease being confined, in the first stage, to the dorsal and lumbar regions. It is only when the cervical region becomes diseased that the upper extremities are affected, and the pupils become contracted and fail to respond to light.

There are severe pains of a lightning-like character,—compared by many to the insertion of a knife or sharp instrument into the flesh of the parts,—especially of the lower extremities. The stomach, rectum or bladder may be affected and, in the early stage, dyspepsia, hemorrhoids or stone in the bladder may be thought of. These pains are common in the first and second stages, and may be present in the third. Ataxia is differentiated from rheumatism or neuralgia by the pangs being momentary in duration and, unlike the pains of rheumatism, do not attack joints, cause swelling or stiffness, but attack small local areas, usually between joints, and are not often repeated in the same spot. Nor do they, as in neuralgia, follow the distribution of nerves, nor along nerve trunks, nor have sensitive points upon pressure along the course of the affected nerve.

Again the pains of neuralgia are referred to the skin, those of ataxia to the deeper structures. Also the latter are confined mostly to the lower extremities and ab-

dominal viscera, while neuralgia and rheumatism attack any part of the body. The skin is for a short time after the attack, tender over the spots of pain, but the most common sensation is that of anæsthesia,—a feeling as if the feet were in cold water; as if the soles of the feet were covered with mud or felt; a feeling of tingling, pins and needles, or as of insects creeping under the skin. The light touch of a pin, hair, or thread may not be felt, while there is pain upon firm pressure. Delayed conduction of sensation is one of the marked symptoms of this stage. The prick of a pin, which should be conveyed to the brain in health in about one twenty-third of a second (sensation traveling, as per Flint, eighty-seven feet per second), is perceptibly delayed. Gowers cites a case, in his practice, of sensation being delayed seven seconds; in another case (Eulenberg) a delay of fifteen seconds. In many cases the pain will increase for several seconds after being felt, and will last for several seconds after the exciting cause is removed.

After a period of a few months,—or it may be many years,—comes the stage of *incoördination of muscular movements.* These are usually manifested in the gait because, as before said, the lesion is, at this stage, in the lower segments of the cord. The loss of patella reflex and ankle-clonus is now marked, although in part absent from the onset of the disease. If the disease, at this stage, involve the cervical region, there will be incoördination of the upper extremities which can be tested by asking the patient to write or place their finger upon nose, eye or ear, or to button and unbutton their clothes. While the gait is labored there is no paralysis; the power of the individual muscle remains while the power for several muscles, or groups of muscles to act in harmony is lost. One of the first things a patient notices is the inability to put his feet upon small objects or to lift them to place them upon a stair, chair or stirrup. One patient I had, complained that he could not wash his face with his eyes shut.

After a time the patient will stand with the feet wide apart the better to keep the balance. Locomotion in the dark, or the hurried crossing of a street, causes a sense of insecurity—the visual sense being necessary to direct the movements. A cane now becomes useful to preserve the balance. As incoördination increases, the power to stand with feet together, though the eyes be open, is lost. The patient now walks slowly, with determination and deliberation, with a jerky, stamping motion, the heel coming to the ground first. Movements of the legs are sometimes unexpected; the toes and foot are thrown outward, and the patient falls. The motion of the limbs in walking has been compared to the swinging motion of a tight-rope performer. The soles of the feet have become deprived of sensation, and the anesthetic condition has extended upward along the legs and thighs which may become dead to all sensation. Dr. Ranney used to teach, and insist upon this fact emphatically, that the symptom thought (by so many physicians) to be pathognomonic of ataxia,—staggering or falling when standing with eyes closed or upon walking backward, goes for naught unless joined with many other symptoms which are common; and that no test is more worthless for this special affection. A patient of his, whose feet were severely frozen, would fall because of the loss of sensation. And the condition of staggering or falling is found in hysterical paralysis, hysteria and myelitis of the posterior horns. A case of hysterical paralysis came under my notice two years since, which had been diagnosed as ataxia upon this symptom alone,—the patella reflex was present; lightning pains absent; sight and hearing abnormally acute. Intracranial diseases, such as Meniere's disease, or attacks of auditory vertigo, cause staggering. Hence, as in all cases of complicated disease, diagnosis by exclusion is the only true and safe way to reach conclusions.

A painful sensation, as of a rope or belt fastened tightly about the waist or body, is often present. This is called the cincture feeling and its location, in a measure, determines the parts of the cord involved; remembering, however, that the nerves, as they pass out of the vertebral canal below the first lumbar vertebra (the cord not extending lower than this), increase the length of their roots; the lumbar, sacral, and coccygeal nerves increasing from nerve to nerve by the thickness of a vertebra.

It is stated that in five-sixths of the cases where the eye is affected, the reflex action of the iris to light is lost.

Atrophy of the optic nerve is the most serious of the eye complications in tabes; of this complication, however, I know nothing.

There is also, in the third stage, vertigo and deafness. The functions of the other cranial nerves are not affected.

The complications are the causes of death,—ulcers; herpes; perforating sores of the foot; retained urine with ammoniacal decomposition; cystitis from use of catheter; fecal poisoning from retained feces; changes in nutrition of bones and joints. One case, which I have, has two large sores where his knees rub together, and he is obliged to keep them apart by cushions. There is sometimes vomiting in the gastric crises, of the peculiar expulsive character seen in brain troubles, —without warning and without nausea. Bed-sores, urinary troubles, and passive pneumonia in bed-ridden subjects, are frequent causes of death. As syphilis is one of the common causes of the disease, gummata, or syphilitic disease of cerebral vessels causing apoplexy, may occur. The disease itself is not fatal, many patients remaining bed-ridden for a long period of years.

Eichorst gives, in tabulated form, the more important symptoms, quoting the following authorities:

	Bernhart. 58 cases	Erb. 46 cases
Absence of patella-reflex	100.0 per ct.	98.0 per ct.
Lancinating pains	79.5 "	92.5 "
Paresis of bladder	74.1 "	81.0 "
Delayed conduction of pain	84.4 "	89.5 "
Feeling of exhaustion	92.0 "	97.9 "
Ataxia	94.1 "	100.0 "
Sexual Weakness	43.7 "	78.5 "
Swaying and tottering with closed eyes	90.2 "	83.5 "

Pathological Anatomy shows sclerosis of the whole posterior column. This explains the cause of delayed sensation, the sclerosis causing such pressure upon the sensory nerve filaments as to partially or completely destroy the axis cylinders.

Etiology.—Ataxia is found more frequently in city than in country life; in families of a neurotic tendency, manifesting such diseases as insanity, epilepsy, and degeneration of the nervous system. Exposure to cold and dampness, traumatism of spine, sexual excesses, syphilis, and some acute blood diseases are accredited causes.

There is quite a difference of opinion as to syphilis being a cause. Some contend that, if it were a factor, no particular part of the cord would be singled out, but any, or all parts would be affected alike; also, that the most energetic antisyphilitic treatment does not effect a cure, while it usually cures in paralysis from brain lesions of syphilis. Others contend that it is one of the most common causes. Hutchinson, the great English authority on syphilis, in a recent lecture, says:— "There are certain affections which appear to be related to syphilis, although not directly dependent upon it, in which it is a predisposing, though scarcely an efficient, cause. Among these I count locomotor ataxia and paralysis of the insane. We seldom see ataxia excepting in those who have had syphilis." Gowers cites fifty consecutive cases in which twenty-nine, or fifty-eight per cent. had definite histories of syphilis.

Men are more prone than women to ataxia, in the proportion of ten to one, showing something in the sex predisposes to it. Possibly due to a man's occupations; to exposure; to cold and dampness; to drink and sexual excesses; as, also, to accidents which harm the spine. It sometimes follows acute blood diseases, inflammatory rheumatism, etc. It is a disease of middle life, rarely occurring during childhood or after the fiftieth year of age.

Prognosis.—Gowers, Ranney, Horsley, and Hamilton claim that some cases can be cured, and we know the great majority can be relieved by proper treatment. If it prove fatal, it is from some intercurrent affection. The duration of the disease is undefined. Sometimes the second stage is never reached, but even with complications some cases last from five to thirty years.

Treatment.—In the first stage, if we are consulted, we should remove all known causes, such as excessive mental work, anxiety and physical fatigue, since they are harmful; and we should insist upon perfect rest. Care should be taken to avoid anything tending to depress the nervous system. If exercise be taken, it should be short of fatigue. Care should be taken to avoid jolting or concussion of the spine. Cold is very injurious, and exposure to a chill results in a rapid increase of the disease. In a medicinal way the digestion and bowels should be attended to. One of the best known remedies to aid digestion and assist the free action of the bowels and kidneys, is the

free use, one and one-half hours before eating, of from one to two glasses of hot water. It causes peristaltic action of the bowels, washes out the stomach, increases the flow of urine and the action of the skin, and soothes the terminal filaments of the nerves of the stomach. The water must be as hot as can be borne. Ergot, one drachm three times a day, combined with some of the bromides most easily taken; citrate of lithia, and, most important of all, the actual cautery, are valuable remedies. Total arrest of the disease and of pain has followed the last named procedure. When there is intense pain, hypodermic injections of morphine or the internal use of Codeine, are of service. In the second stage the bromide should be stopped. Should there be the least history or suspicion of syphilis, the mercury and chalk mixture, (which, Hutchinson says, "is the only form in which to use mercury for a long time"), which we also use in the first stage, should be continued. Nitrate of silver in pill form can be used, not pushing it, however, to the extent of staining the skin. Static electricity, cautery, and, if the bladder be affected, belladonna should be used. Hammond advises the injection of atropia. Suspension, causing separation of the vertebræ, is highly recommended, but the results have not proved as beneficial as at first reported. If there be any retained urine, the catheter should be used. The bladder should be washed out with a fountain syringe and soft catheter, which the patient can be easily taught to use. Arsenic is a very valuable remedy; used best in the form of Fowler's solution. Bed-sores and all other complications should be watched for and treated as they arise.

CLINICAL LECTURES.

TUBERCULOSIS OF THE SHOULDER JOINT; TONSILLOTOMY; TUBERCULOSIS OF THE HIP JOINT.

JOHN B. HAMILTON, M. D., LL.D., Chicago.*

TUBERCULOSIS OF THE SHOULDER JOINT: RESECTION BY A NEW METHOD: TEMPORARY RESECTION OF THE ACROMION.

Gentlemen: The first case that I shall present to you to-day is one of tuberculosis of the shoulder joint.

Tuberculosis comes to this clinic so often that it is hardly worth while for me to go into the details of the pathology of the affection further than to say, that it constitutes, roughly speaking, about ten times as many cases of disease in this clinic as come from any other single cause—that is in the form of tuberculosis of bones, joints, glands, or some portion of the body.

In the case of the patient before us we have a sinus on the anterior border of the axilla, and another one posterior to the axilla at its outer border; each of them extending directly upwards for three and a half to four inches on either side of the humerus. I cannot pass a probe directly into the shoulder joint, and yet I have no doubt that the pus in this case proceeds from the shoulder joint. This man seems generally sound, but we notice atrophy of the muscles of the arm. The right arm itself is helpless as compared with its fellow. And for nine years the patient has had these two openings, at times closing, at others breaking out and an abundance of pus being discharged through these fistulous tracts.

It can be but one thing. We might have, it is true, a foreign body, such as a projectile from a pistol, or a gun-shot wound in the head of this bone, but the history of the case shows there has been nothing of that kind. He states that about nine years ago he received a bruise on the shoulder over the deltoid muscle. But there is no apparent connection between that bruise and the existing sore, except sometimes we know that tuberculosis which is latent, is suddenly lit up, propagated and developed by mechanical

* Professor of the Principles of Surgery and Clinical Surgery, in Rush Medical College.

violence, or is produced by irritation of some sort,

We are confronted with the problem today, how best to stop this constant drain of the system without seriously impairing the joint. On examination I find he is able to raise a chair with his hand. He can raise the elbow nearly to a level with the shoulder but the arm is disabled almost totally. We must plan an operation in this case which will not deprive him of the use of the arm, at the same time we must destroy the pyogenic center.

I propose then to make an exploratory operation. I shall cut down by the method proposed by my colleague, Prof. Senn, in his recent work on "Tuberculosis of Bones and Joints," making a temporary resection of the acromion. So far as I know, no surgeon has as yet performed it. We will test its feasibility at this time; make the operation, and expose the portion of the joint surface that is the probable seat of the disease.

In making a resection of the head of the femur, we take a chisel, lift up the trochanter, leaving its muscular attachment, so that when we cut off the head of the femur we can then return the trochanter and the rotation of the limb is perfect when the trochanter again unites. I have a patient, at present under observation in the Presbyterian Hospital, who can turn his toes in and out as well as he could before the head of the femur was removed. That is accomplished by preserving the muscles intact, making a temporary resection. We do the same thing in the case of the olecranon and other bones.

I shall, in this case, make a straight incision, commencing just above the acromion process, extending through the skin, passing a little backward toward the posterior border of the axilla. I shall then meet that with another incision, passing down toward the spine of the scapula. In this way I propose to fully expose the acromion process, and then make a temporary resection of that process. This should expose the capsule of the joint with the least injury to the soft parts.

Several methods of opening this joint have been proposed and practiced. There are perhaps ten or fifteen different lines of incision. All of them are planned to avoid the great vessels of the axilla; some are made on the anterior surface; some directly through the deltoid on the external surface.

I shall first locate the acromion. Locating it, we make a transverse incision just above it and then a long one just behind the acromion, passing down along the external border of the deltoid muscle. You will notice that the probe on the anterior surface passes directly upward for a distance of three and a half to four inches; there is another opening on the posterior border which passes in the same direction. So the inference is clear that the source of origin of this pus may be the shoulder joint. Please remember, that in this operation it is not proposed to detach the muscle from the bone. On the contrary we propose to preserve its bony attachment.

I now with the chisel cut through the acromion process, and you will see that the attachment of the deltoid is practically untouched. Theoretically we shall be able to come directly upon the capsular ligament and, as you will see, we shall be able to enter the joint from above. Observe that the pus cavity is directly under the acromion in this case and that I have now come upon the capsule of the joint. I shall open it and pass my finger over the joint surfaces. I must be careful, in opening the joint, not to interfere with the long tendon of the biceps, or the circumflex nerve. In order to prevent that we shall determine where the biceps is located in its groove and, in order to throw it out of its position so far as may be, we will rotate, bring the humerus across the body and enlarge the incision. The portion of bone which you see is the acromion process of the scapula which I have turned up. The pus cavity I uncover when I lift the acromion. We probably do not see the extent of the carious process, so before proceeding to the more radical method of turning the head of the bone out, I will remove the pus. The difficulty attending this operation so far seems to be lack of room to fully expose the head of the bone. I will increase the room by further turning up the deltoid flap. We are now breaking into pus cavities all about this joint. The head of the humerus is now well uncovered, or rather the external face of it is. We will separate the attachments from the glenoid cavity by throwing the arm directly across the body, then making rotation outward. The bicipital groove is now exposed to view. I shall cut the fascia and the tendon sheath so as to loosen the biceps along the groove and not cut it,

for by so doing the circumflex nerve should be thrown over with it.

Pus comes directly out of the bone the minute the chisel strikes it. We have to deal then with a case of tubercular osteomyelitis of the head of the humerus. The bone is very soft. The head of the humerus is honeycombed with pus, and so soft that the slightest touch suffices to break it down. You will see that the exposure of the joint has been perfect. Prof. Senn's theory has been carried into practice here with success so far as reaching the joint is concerned, which, of course, is the main thing.

I have now scraped out the carious bone, removed the head of the humerus and shall smooth the glenoid cavity, which seems to have been infected, pack it with iodoform gauze and then clean it out. First rub it well so as to have the iodoform fully penetrate it. Fill these surfaces with iodoform powder, so that any tubercular deposit, which may have escaped being scraped out, shall be reached by it. I now take the soft parts that are involved in the disease and scrape the pyogenic surface so as to leave the tissues exposed to view. We will pack the cavity with iodoform gauze, carefully and tightly, and leave one end projecting at the most dependent portion of the wound, so that we can remove it at pleasure, and it will at the same time serve for drainage. I shall now tie the vessels if they seem to require it, which they do not, and then bring back the deltoid and suture the acromion section which was made. It is a temporary resection. The deltoid is preserved.

This man will be able, hereafter, to raise the arm precisely as he could before the operation, which is the particular point to be gained by a temporary resection of the acromion. I passed the needle through the fascia covering the bone and through the periosteum on each side of the incision, so we are bound to bring the acromial surfaces directly in apposition. If I had this operation to do over again, I should throw back the deltoid and dissect it off from the face of bone in the beginning. This would shorten the operation one-half.

On examination of the removed bone, we find that the pus originally came from the centre of the head of the humerus. You can see it as a pulpy mass, evidently tuberculosis of the humerus. The tissues immediately about were little involved except that they afforded depots and an outlet for the pus. At the point where the drainage is inserted I shall put in temporary sutures, leaving a long loop so that they may be tightened subsequently, constituting what is termed secondary sutures. I shall now complete the operation by passing a small-sized sharp spoon into each of these original openings and scrape out the fistulous tract. The upper end of it was thoroughly done when the flap was turned up. I am satisfied that this operation will be one of the most common for reaching the joint. It is very easy of performance, and I believe it will be found to be more successful than others. The wound is to be thoroughly cleansed; the arm fixed to the side; cotton and gauze placed next to it, and then by a plaster-of-Paris roller the shoulder is fixed in position for three weeks. We may cut a fenester in the plaster if we find a rise in temperature, but if there be no elevation of temperature the first dressing will remain for a period of one week.

TONSILLOTOMY.

This child has a sore throat and a swollen tonsil. I have here the tonsillotome of Fahnestock. It consists in a ring with a double spear for fixing the tonsil and a guillotine blade which pushes through when the tonsil is fixed. It is intended for the partial removal of the gland when it becomes permanently hypertrophied. I think the surgeon is not justified in removing tonsils when swollen, and in a state of acute inflammation. But when they become permanently hypertrophied, and the condition has existed for some time, and there is no longer any probability that the gland will resume its normal size, then the surgeon is justified and should remove the projecting portion of the tonsil. I prefer in my office, when I am required to do the operation, to take a volsella forceps with the claws at the side, open the mouth, seize the tonsil, and cut it off with a curved bistoury—a more surgeon-like instrument than this machine I am now using.

TUBERCULOSIS OF THE HIP JOINT—TEMPORARY RESECTION OF THE TROCHANTER.

I have not recently examined this child and I do not know, therefore, what opera-

tion will be performed, but we will find out as soon as the examination is completed.

She has been in the hospital several times; sometimes having extension apparatus applied, at other times remaining in bed with weight and pulley. But all of that kind of treatment, which is simply palliative and intended to hold the joint surfaces apart while the child is under tonics and other means of treatment, has been without avail. She now comes back to the hospital unable to walk, unable to move the hip without severe pain—so painful in fact that I propose to conduct the examination under anæsthesia, perform whatever operation is required and can be done at this time.

On turning the child on the side you will notice a fistula posterior to, and a little below the trochanter. We will take the probe and ascertain the direction of the fistula. I find that the probe passes directly into the joint. There is, therefore, only one way to treat this joint successfully at this stage, that is, to make an opening into it, remove either the soft parts by arthrectomy, or resection of the bone, or both, according to the extent of the disease. If this girl were an adult instead of a child, there would be no objection to performing a typical resection, but in children an atypical one should be the rule.

I will content myself by cutting down upon and performing a temporary resection of the trochanter. We simply cut down upon it by linear incision, with the chisel lift it up with its muscular attachments, and the neck of the femur is fully exposed. We are then able to reach the joint. I make my incision directly over the trochanter, slightly curved, but passing deeply down to the bone. I have separated the soft parts from the bone as much as is required to make a linear incision to the trochanter. I have separated the trochanter from the femur with the chisel and the incision is directly on a level with the upper surface of the neck of the femur. I shall turn the trochanter directly upward, which gives complete access to the capsule of the joint. I now separate the neck of the femur from its attachments, open the capsule and expose the joint. Now, by rotating a little, I can put my finger directly into the opening and feel the amount of erosion that exists, with the head of the bone still within its socket. If it be not too great, I prefer to do but little else than to make an opening into the joint and provide for the injection of iodoform.

Remember what I have previously said about resection in children. We avoid them whenever possible, as we stop the growth of bone by resection; whereas, if we can perform an arthrectomy, or, by gouging out the carious portions of the bone preserve the joint, we will have accomplished very much more for the child.

I find a sinus with a roughened surface on the face of the bone, and I shall gouge out this opening first, as the bone is quite soft. I shall be able to do it without using the knife. This is being done subperiosteally. I am passing a gouge longitudinally along the neck of the femur to the head of the bone, and removing the carious surface, which I will soon have complete access to, piece by piece. The pus, which is very plentiful here, exudes from the bone in several places, and we have, as in the shoulder case, evidence of its commencement in the medulla of the bone and its cancellous structure. I find that the acetabulum itself is involved, and the rim of the acetabulum will have to be scraped out. This I am doing. The process is tedious. In the removal of these fragments of bone you will find it expedient to use the finger as a guide, keeping it on the fragment while the instrument (the sharp spoon) is being fixed. In this way you avoid unnecessary damage to the soft parts, and it enables you to have control of the operation at nearly all of its stages. The specimen which I show you, as now removed, consists of half of the side of the neck of the femur and half of the head. You will see how the disease has progressed around the head of the bone. The white, glistening portion is the articular surface of the head of the femur; the eroded portion of the other side is where tuberculosis has eaten into the head of the bone. We now irrigate the joint as there is a great deal of eroded surface; the wound is dusted with iodoform powder, and, as before, iodoform gauze is inserted for drainage. There is a sinus underneath the bone in the soft parts extending into the cavity of the acetabulum, which I thoroughly scrape with the sharp spoon. I now bring the trochanter back into its place, leaving a drainage of gauze from the most dependent portion of the

wound which passes directly into the joint. We sew the trochanter into position with very heavy catgut. I pass a needle through the periosteum, the fascia and sheath of the muscles attached to the trochanter and through the same structures on the shaft of the femur, thus bringing the parts into perfect apposition. The power of rotation of this child's thigh when the trochanter and bone unite, which will be in about three weeks, will be as perfect as before the operation. Care should be taken that no tension is put upon the stitches that can be avoided. The limb should be fixed in a poposition which brings the bone together without tension. The packing, which is being inserted, is in the intermuscular septum where the pus formed during the progress of the disease, and which has been thoroughly scraped and irrigated. You will notice there has been very little hemorrhage. Hemorrhage is much less when the trochanter is resected than in the other operation.

The dressing in this case will be precisely as in the former one. The parts about the wound are to be well cleansed; iodoform gauze and antiseptic absorbent cotton applied, and a plaster cast over all.

The history of these cases after resection of a joint, performed as these were, is generally one of uninterrupted convalescence. Occasionally we have a sinus formed directly in the tract of the wound, due, undoubtedly, to some pyogenic reformation,—some bacterial colonies which were left in some undisturbed pocket at the time of the operation. But in the majority of cases we do not expect any result other than steady progress toward uninterrupted convalescence. It is a crippled limb, but it was this before the operation was performed. We have stopped the pus formation. More than that, it differs from an ordinary resection in this particular: after the old methods of resection, the limb hung like a flail; while it might be as powerful as before, especially after resections of the head of the humerus, yet the power of rotation was completely lost; and in many instances the power of elevating of the elbow to the level of the shoulder was lost. In our case of temporary resection of the acromion, I have no doubt the power will be as perfect as before the operation.

COMMUNICATIONS.

TECHNIQUE OF SUPRA-PUBIC CYSTOTOMY.

JAS. S. CHENOWETH, M. D., Louisville, Ky.

I would like to present as a basis for discussion, a few points relative to the technique of supra-pubic cystotomy. I have been impressed, in all of these operations that I have seen, with the importance not only of a strict regard for the indications to be met in each individual case, but also with the importance of a strict attention to detail in meeting them, if we would receive the greatest possible good from our operation.

Viewed from the standpoint of the technique, I think we can properly divide our cases into four general classes.

The *first* class includes the recent cases of stone and foreign bodies and small pedunculated growths, where the bladder is only moderately or not at all diseased.

The *second* class includes the neglected cases of the first class, where severe inflammatory changes have taken place in the bladder walls.

The *third* class includes the cases requiring removal of tumors or prostatic outgrowths, or prolonged drainage for cystitis.

The *fourth* includes that not inconsiderable number of old neglected strictures of the urethra in which a guide cannot be passed for the perineal operation, and retrograde catheterization of the urethra is desired.

In the first class, no especial preparatory treatment is requisite beyond emptying the bowels by laxatives and enemata, irrigating the bladder with boric acid solution and shaving and cleansing the abdomen.

The anæsthetic—preferably chloroform—being administered, an oval rubber bag with the tube attached is introduced into

the rectum. By means of a soft catheter and a hand syringe the bladder is filled with warm boric or Thiersch solution, the quantity being regulated by the known capacity of the bladder and the sense of resistance imparted to the hand; this is retained by an elastic band around the penis and a clamp on the catheter. The rectal bag is now slowly and carefully injected and the bladder may be felt in contact with the abdominal wall above the pubis. A three inch incision in the median line, just above the pubic bone, carried down between the recti and pyramidalis muscles exposes the prevesical space and the presenting bladder wall covered by a thin membrane containing more or less fat. This fat, which contains the peritoneum, is rolled up from the symphysis, care being taken not to disturb the lateral attachments of these loose tissues. This little manoeuvre is often much abused, and operators, in a frantic effort to avoid the peritoneum which is in no danger if the bladder and rectum have been properly injected, so loosen up the attachments behind the symphysis and around the neck of the bladder that urinary infiltration and consequent cellulitis is inevitable.

The bladder being exposed, any large veins on its surface in the line of proposed incision are ligated with fine catgut by means of a sharply curved needle; and a strong silk ligature is passed deeply into the wall of the bladder, which is incised just below by a clean thrust of the knife. This ligature serves to hold the bladder in contact with the abdominal wall after the incision, and diminishes the risk of tearing loose the anterior attachments while punching around in the bottom of the pelvis trying to find the opening in the now collapsed organ.

The incision in the bladder should be of sufficient length to permit of the easy removal of the foreign body without tearing and bruising the edges of the cut. Guided by the ligature the finger is quickly introduced and the body removed. After thorough irrigation the bladder, being still held up and steadied by the ligature, is closed with numerous interrupted sutures of over prepared catgut carried down to the mucous coat; or in some cases, an oval surface may be denuded around the incision and the broad, fresh surface thus formed united by two rows of continuous suture. A small drainage tube is laid over the line of suture and brought out of the lower end of the external wound, which is closed down to this point. A soft catheter introduced through the urethra and tied in, completes the operation.

In the second class, with inflamed, contracted bladders, effort should be made to cleanse them and at the same time gradually dilate them to a reasonable capacity before operation, and unusual care should be taken against rupture when the final distension is made under anæsthesia. The operation is completed as in the former class up to the point of closing the bladder wound.

It being evident that the wound of an acutely inflamed and contracted bladder will not unite primarily no attempt should be made at closure, but drainage should be free. This may be done by a tube carried to the bottom of the bladder and retained by fastening to the skin, or by a perforated hard rubber plate with straps carried around the abdomen. The end of this tube may be left long and drain into a vessel at the bed side. If the tube causes much pain and is forced out it is often impossible to replace it; this seems to be of little moment as far as the bladder is concerned, as it will drain and can be thoroughly irrigated without it, but the patient is kept continually wet by the flow of urine.

In the removal of tumors or prostatic outgrowths from the bladder by the suprapubic method, the rectal bag should be distended as far as safety will permit, thus forcing up the base of the bladder and greatly facilitating the work.

The Trendelenburg position is also of great service here, bringing the parts well into view. After the removal of these growths there always arises the necessity for thorough drainage for a considerable length of time, and, in the case of old cystitis, the drainage may have to be permanent. This drainage, in my experience, cannot be well accomplished without fastening the bladder to the abdominal wall. The tube almost invariably slips out, or has to be removed on account of clogging or becoming encrusted with urinary salts, and it is often impossible to replace it through the long sinus running down to the bladder. This sinus contracts rapidly and, unless the obstruction at the bladder neck has been perfectly removed,

the cystitis will return, and not only will there be no benefit derived from the operation, but a small discharging sinus will add misery to an already miserable being.

In opening the bladder for retrograde catheterization of the urethra in impermeable stricture the rectal bag should not be used. The bladder is usually diseased and distended and the danger of rupture is great. A little care in stripping up the prevesical fat is all that is needed to avoid the peritoneum. The opening should be small and, as a rule, immediate suture practised, free drainage being kept up through the perineal opening until union is complete.

NURSING IN TYPHOID FEVER.

JOHN C. HOLMES, M. D., Cranbury, N. J.

To the country physician the nursing of typhoid fever is of particular interest, as he so frequently has considerable difficulty in obtaining a competent nurse in fever cases.

There is no disease in which, during the entire course, every organ of the body is so liable to become disordered as in typhoid fever. Therefore good nursing and particular attention to all of the minor details is absolutely essential.

When a case of typhoid fever occurs in a family, the first step to be taken is to isolate the sick person as much as possible from the rest of the household; this is necessary for two reasons, first, for the comfort of the patient, and secondly, for the safety of the other members of the family.

A large room should be selected, and one which will afford means of perfect ventilation.

The windows should be raised about four inches, and a board fitted tightly at the bottom, thus giving a free access of air over the top of the lower sash, and avoiding all draft.

This ventilation should be continued day and night, even in the coldest weather. A uniform temperature should be maintained from 60° to 70° F.

In winter an open fire place or grate is to be preferred to any other method of heating a sick room. Let the patient have as much covering on the bed as is necessary, but keep up the free ventilation at all seasons of the year; fever patients are not liable to take cold.

Do not admit visitors at any time during the course of fever—mental quiet is as necessary as bodily rest. Remove all carpets and curtains—in fact all that is required in a "typhoid room" is the bed, one chair, a small table and an alcohol lamp. Have a large covered clothes basket in an adjoining room, in which all soiled linen may be at once placed and immediately carried out of doors; wash these clothes separately from the clothing of others, and direct the wash water to be emptied at a safe distance from the house and well.

The sheets should be changed every day, and this can be done easily by folding the under sheet close to the patient, spreading one side of the bed over, and then gently lifting the person over on the clean side, at the same time removing the soiled and smoothing out the clean sheet.

The aphorism, "cleanliness is next to godliness," is indeed truly hippocratic, and most assuredly applicable in typhoid fever.

Twice a day wash the face, hands and limbs and, if advisable, even the entire body with lukewarm water to which add a little alcohol; in cases of extreme depression, alcohol or whiskey may be used alone; a sheep's wool sponge is the best for use in washing the body of a sick person.

All excretions from a fever patient should be received in a previously disinfected vessel and at once removed out of doors, at least one hundred yards from the well and house, and there buried—a fresh layer of sand spread over each time.

Now in regard to disinfectants, avoid carbolic acid on account of the unpleasant odor and the tendency to nauseate the sick. Platt's chlorides is one of the very best disinfectants; it is perfectly odorless and can be procured at a very reasonable price. Chloride of lime, used according to the printed direction on the box, is always good. A solution of copperas can be used to wash out all vessels which receive the

excrement, and it is a good plan to leave some of this solution in the urinal and bed-pan after they have been cleansed and returned to the sick room.

As to light—do not keep a sick room in darkness (unless there should be brain complications) in fever or any other disease—light and sunshine are as essential to the sick as to the well.

If a lamp is used at night, do not turn the wick down, on account of the gas which will be sure to be thrown off, but shade the light so that it will not disturb the patient.

One of the worst torments of fever is thirst, therefore give plenty of cold water; little at a time but frequently. A swallow of water will moisten the mouth just as well as will a glassful.

Drink should be given even when it is not asked for, as fever patients need just as much, and sometimes even more than when in health. Mineral water, lemonade and thin barley water are all exceedingly grateful.

Keep ice in a covered vessel wrapped in a woollen cloth and in the next room, and always break the ice with a pin. If coal is used for fuel, put it in paper bags, and place it on the grate—thus you avoid a noise which is sure to attract the attention of the sick.

Never attempt to use any force, or even to argue with a fever patient in order to have one take either food or medicine; the sick are frequently very unreasonable, and if the mind is disordered it is worse than useless to endeavor to reason with them. When anything is refused put it aside at once and appear to be perfectly satisfied. In five minutes offer it again, and nine times out of ten it will be taken without any complaint.

Never say to the sick, "now it is time to take your medicine," or "will you take the medicine now?"—do not use the word medicine. Prepare it in silence, take it to the bedside, and say, gently but firmly, "swallow this please." It is not to be wondered at, that invalids have a feeling of disgust come over them when they hear the rattling of spoons and see the nurse making elaborate preparations for the advent of each dose of medicine. I have seen the patient vomit at the sight of the glass and the noise of the spoon.

Always remember that a sick person can never be spoken to too kindly; typhoid fever patients are frequently in a dreamy state of partial consciousness from which a harsh word would arouse them to the wildest frenzy.

The nurse should be a veritable sphinx as far as all conversation is concerned. Questions should be answered in a monosyllable, without any remark or comment.

Always pretend to remove any imaginary thing from the room if so requested by the patient; never declare that "it is nothing"; you can not convince one with a disordered brain that an hallucination is only imagination.

Nourishment should be given at regular intervals, and the physician should not only give explicit directions as to the kind and quantity, but should make out a "time table" for both medicine and diet.

The patient should never be allowed to have anything to eat or drink without the permission of the doctor. There is no disease in which the slightest indiscretion in regard to diet may prove so suddenly fatal as in typhoid fever—it requires but little to turn an almost evenly balanced scale one way or the other.

Do not allow the patient to rise for any purpose whatever from the beginning of the disease until convalescent; many fatal cases of syncope have occurred upon assuming an upright position even for but a moment.

Watch fever patients closely; never leave them alone—many apparently perfectly manageable cases have jumped from a window, or committed suicide when left alone for a few moments by the nurse.

It is best always to have two nurses, one by day and one for the night. Never trust the nursing to kind friends or good neighbors—who, while they may be overflowing with sympathy, have not the routine of the case, and therefore can not do as well as a regular attendant.

I have had seven cases of typhoid fever where I have found a new nurse on duty almost every day, and have frequently been unable to ascertain the exact condition of the patient during the night, as the nurse "had gone home to get a little sleep," and left no other report of the case than this, "they were about the same as usual."

If milk is used, keep it outside of the sick-room until it is required; never allow milk to stand in a typhoid room of all

others; prepare the exact quantity needed and use it at once—this direction should also apply to all meat-broths.

Do not tell a fever patient any unpleasant news,—give them to understand that everything is going along nicely.

Always speak encouragingly and hopefully, giving the sick the benefit of every doubt. There is no disease in which a person can sink so low, to the very border and in the shadow of the grave, and still recover.

Never "give up" a fever case, as changes for the better may occur when least expected, and even under the most unfavorable circumstances. I have seen cases which I feared would not live six hours, and have had the satisfaction of seeing them recover. Avoid all those people who make a business of "*nussin*," they believe they know it all and are far more liable to overdo matters than really to neglect. Secure an intelligent man or woman,—one who has either an established reputation or a diploma from a training-school.

Good nursing is, indeed, the *sine qua non* in typhoid fever—without it medicine is of little value. I would prefer an intelligent nurse and no medicine whatever, rather than the attendance of an entire faculty and an ignorant or careless nurse.

Human life is far too precious to trust in the hands of unskilled persons; to err at such times is but too frequently fatal, and ofttimes the cause of life-long regret, which, while it may be without true cause, nevertheless may leave the unpleasant thought that perhaps something was left undone.

The constant attention to all of the *little things* always gives the best results in nursing.

A CASE OF CEREBRAL SURGERY.

W. C. DUGAN, M, D., Louisville, Ky.

I have a case of cerebral surgery that I would like to mention. A lady about fifty years of age has had great pain in the head for eight or ten months, and it has steadily increased. She has been treated by a number of physicians on various lines and she has grown steadily and rather rapidly worse. Her hearing was at first but slightly involved, but latterly to such an extent that she could hardly hear at all. During the last few weeks I am confident there has been marked impairment of intellect.

I saw her for the first time several months ago, and then did not see her again for about two months; meantime her physician asked Dr. Dabney to make an examination, and he reported double-choked disk, the right more marked than the left. Later she had partial paralysis of the right leg, twitching of the right side of the face and incomplete loss of sensation of the right arm.

Diagnosis of tumor was made, its most probable location being in the left side about the upper part of the fissure of Rolando. She had two convulsions during this time, whether unilateral or bilateral I am unable to say, but they were rather severe and were followed by considerable stupor. Exploratory operation was advised for the purpose of finding the tumor, the understanding being if it could be removed it would be done.

A very large semi-circular incision was made over the left parietal bone, the flap turned down leaving the periosteum intact. After going through the periosteum and turning it back separately, we took a large sized trephine expecting to take out a large button, but found it slow work, the skull being very thick. I then decided to take out a smaller sized button. The bone was removed and the membrane bulged up almost half way through the skull, very tense and feeling almost like wood. I then took a chisel and mallet and cut out the entire two inches of bone, the size of the original trephine. The tension was so great that the membranes came up almost on a level with the outer part of the skull. The dura was then incised and to my very great surprise,—and perhaps I should say my chagrin,—the brain just swelled up, almost like quicksilver, through the incision in the dura. There was a mass of cerebral tissue as large and thick as your finger pressed through the

opening in the dura, and the constriction was so great, and the tension from within so much, that it produced intense engorgement. The dilemma was not one to be envied, I assure you. I did not know how to close the dura. Knowing that there must be something to account for the great pressure, I explored with a hypodermic needle and found no fluid. I then took a groove director and passed it down to the ventricle, and found a large quantity of fluid in the left cavity—at least three ounces, and perhaps more. As the fluid flowed through the groove, the brain settled back in its place, and at the conclusion of the aspiration I was able to pass my finger around the dura, palpating the brain so as to ascertain whether there was a tumor anywhere. No tumor was discovered. I then thought best to pass the groove director through the septum to the other ventricle to see if any fluid existed there. This was carefully done, but no fluid found. The dura was then closed, and the scalp sutured, no drainage being used, and the patient dressed and put to bed. She reacted well from the operation, there being no shock.

She has had some little trouble since with loss of speech, but she is able to articulate some sounds distinctly and intelligently. She has suffered very little pain since the operation, and has been doing very well. Instead of finding a tumor we discovered an accumulation of fluid in the left ventricle, the pathology of which I am unable to give. The fluid seemed to be perfectly clear, but whether it was tubercular or otherwise I am unable to say. The future of the case is purely one of conjecture; I am not prepared to say what the outcome will be. Her physical condition is good; the operation was done one week ago, and she sat up to-night and is suffering no pain. The paralysis has been relieved, but her hearing has not returned. I cannot help believing that the trouble will return and that the end is not very far off.

The paralysis was relieved immediately after the operation. Sensation now seems to be hyperesthetic. Before the operation, as she could not hear, her family would write messages on paper and she would look at it for a long time and eventually she would understand it. She would wait four or five minutes before answering a question, showing that her intellect wa greatly impaired.

I left the bone out for two reasons: First, it could not have been replaced, as, after taking out the button with the trephine, the opening was considerably enlarged with the chisel; further I would have left the button out anyway so as to have the advantage of that amount of lack of resistance, and, in event of the fluid re-accumulating it can be aspirated with less trouble. The opening left in the skull, as nearly as I can judge, was about two inches in diameter. The only hemorrhage experienced was from separation of the dura. If I had not explored the brain, I would never have been able to have brought the dura together.

LIGATION OF THE ANTERIOR TIBIAL ARTERY ABOVE THE ANKLE JOINT.

A. O. STIMPSON, M. D., C. M., Thompson, Pa.

Frank Allen, aged about thirty-three years, while chopping in the woods on the 9th of December, 1892, accidentally made a deep cut with an axe in his right leg, about one and one-half inches above the ankle joint, and on the outer side of the leg. The cut was apparently not a severe one, the incision being only about one and one-half inches long. He had on at the time a pair of felt boots (such as choppers and woodmen generally wear) and the axe, which was broad bitted with angular corners, having a very thin and sharp edge penetrated the flesh much deeper than one would naturally suppose.

After the accident his companions got him to the house as soon as possible, and resorted to ordinary domestic means to arrest the hemmorrhage, by bandaging and the use of "puff-balls" as a local styptic.

No further difficulty was experienced with the wound until the next evening, when it commenced to bleed profusely.

I immediately applied the rubber tourniquet over the popliteal space, using as a compress a rubber "anti rattler" for wagon shafts. This controlled the hemmorrhage completely. I then tied the injured artery (anterior tibial) with an iron dyed silk ligature, But the operation, having been done by lamp light, was not a success. On December 11th (at night again), a messenger came for me in great haste, saying that "Frank was bleeding to death." I hurried to the house and found that he had indeed lost so much blood that he was very weak. I immediately applied the tourniquet in the groin. This checked the bleeding at once, but I concluded then I would wait until daylight before ligaturing the wounded artery.

As soon as there was light enough, with the aid of a neighbor, I enlarged the incision upward toward the knee, and with a No. 11 iron dyed silk ligature I tied the artery the second time, using a sailors knot to prevent the loop from slipping.

I had no trouble from hemmorrhage after that, but a wound remained that could only heal by second intention, or by granulation. In treating the granulating surface I used iodoform gauze, dry calomel and campho-phenique.

A Short Umbilical Cord.

J. B. CARRELL, M. D., Hatboro, Pa.

On Dec. 28th, 1892, I delivered a woman, æt 38, of her fifth child. There was nothing unusual about the case until I attempted to move the infant from its moorings.

The child was drawn so closely to its mother that it was difficult to tie the cord; in fact the second ligature was applied by pushing up the external genitals. When the cord was cut it disappeared up the vagina. I could not wrap the cord about my finger to make traction on account of its being too short; so I effected removal of the placenta, which had been expelled into the vagina with the expulsion of the child, by hooking my finger into the body of placenta and making external pressure with the other hand. Upon examination I found a cord seven and one-half inches long.

This is not the shortest cord on record. The shortest I find mentioned was two inches. Cazeau and Tarnier say: "The cord varies greatly in length at term; generally it is from twenty-one to twenty-three inches; some have been observed, however, from six inches to five feet; others, still more rare have reached five feet nine inches in length. I delivered a woman with the forceps, June 23rd, 1841, in whom the head had been retained above the superior strait, and where the cord was only nine inches long. These extremes are very rare; nevertheless, they are not the utmost varieties the cord may offer in its extreme limits, for it has been known not to exceed five inches, and has even been as short as two inches." With the expulsion of the child the placenta was expelled from the uterus into the vagina. Had such not been the case, the short cord would have interfered with the delivery of the child.

An exchange says that a new and simple method of preventing bed-wetting by children is proposed by Dr. Von Trenton, who simple raises the foot of the bed so that the child lies on an incline with the opening of the bladder uppermost. This is based upon the theory that the urine escapes from the bladder while the child is asleep. The remedy is simple and worth trying; the only difficulty is that most children have a natural fancy for rolling about in bed and will cause themselves to sleep with the head at the elevated end of the bed as often as otherwise. —*N. West Lan.*

Sugar in the urine is no more a proof of diabetes than albumen is of Bright's disease; and it is a great mistake to base the diagnosis upon the one point alone. The presence of the sugar may be due to transient nervous conditions, to temporarily defective action of the liver, to excess of sugar in the diet, as when a new clerk goes into a candy shop, or to a disturbance of the general system like that caused by the retention of the milk in woman who have suddenly stopped nursing. Gout, syphilis, heredity and renal disease may also cause glycosuria without diabetes. Ord, of London, says that while he has not frequently met with carbuncle or phthisis in glycoruria, they are common in true diabetes.—*North Lan.*

SOCIETY REPORTS.

THE SURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting of December 12, 1892.

The President, Dr. A. M. Cartledge, in the Chair.

Dr. W. C. Dugan reported "A Case of Cerebral Surgery" (Page 130).

TWO CASES OF STERILITY FOLLOWING GONORRHŒA.

Dr. E. R. Palmer: A young man, having been married three years, came to me a year ago with gleet and stricture of the urethra, with the statement that his wife was barren; that he wanted to be cured; that his wife also had trouble which he believed she had contracted from him, and that he wanted me to treat her also.

I operated on him for stricture by the Otis' operation, treating him for a long time and, at the same time treating his wife, who had chronic vaginitis and chronic endo-cervicitis with a deflected, fixed uterus,—a condition that we nearly always find where a woman had contracted gonorrhœa and the deeper membranes had been invaded.

This man was entirely cured of his gleet and stricture. His wife was very promptly relieved, her vaginitis disappeared, the discharge from the uterus ceased and she was in excellent condition. I saw the gentleman a few days ago, and he said he was happy to report that he was the father of a fine girl.

No. 2. About six months ago, when the pregnancy of the patient above referred to was well assured, another man employed by the same corporation, came to my office with his wife and asked me to make an examination, try to determine why his wife never had any children, and treat her for barrenness. I told him this was rather out of my line, and suggested his consulting another physician. He said he had been married two years, and his wife had never conceived. As I had treated Mr. and Mrs. So and So, who had been married three years and the wife was pregnant, he wanted me to see what could be done in his case. I made inquiries as to whether either of them had ever had any trouble of a venereal nature, and he replied that they had not. I took them both over to Dr. Anderson's office and they were examined separately.

The woman was a magnificent specimen of womanhood, weighing about 150 pounds, apparently in perfect health, vagina and womb normal in position and size. In other words her entire sexual apparatus was in a perfectly normal condition.

I then took the man into an adjoining room and he confidentially gave me the history that several years ago he had contracted gonorrhœa with double epididymitis, but stated that he had been cured for a long time before marrying. I instructed him to have connection with his wife and bring me some of the semen for examination. He did so and it was found to be utterly devoid of spermatozoa, proving beyond all question why his wife had never become pregnant.

It is stated that in ten cases of barrenness the woman is at fault seven times, the man three.

Dr. Jas. S. Chenoweth read an essay The Technique of Supra-pubic Cystotomy (Page 126).

DISCUSSION.

Dr. W. O. Roberts: I have had considerable experience in the operation of supra-pubic cystotomy for stone, for cystitis, for tumor and for draining the bladder in old cases of enlarged prostate. In some cases I have used the bag and in others operated without it. I believe that we can get along just as well without as with it. Where we want to operate on the prostate, I think we can be better aided by an assistant introducing his finger into the rectum and pushing the prostate upward and forward, than with the bag. I have never found it necessary to tie any vessels in the bladder wound. As soon as the bladder is emptied, distension of the vessels will disappear and the hemorrhage will cease. I reported, I think to this Society, some time ago a very interesting case, a patient of Dr. Palmer's, where I operated for tumor of the bladder by the

supra-pubic method. The tumor in this case obstructed the flow of urine through the urethra; after closure of the supra-pubic wound the man was able to pass water by the urethra, throwing it three feet from him. This is not the usual result in such cases. As a rule they do not recover the power of completely emptying the bladder through the urethra.

Dr. E. R. Palmer: I am forced to believe that the modern operation of supra-pubic cystotomy will eventually find its proper place to be where it has been fully determined that the old-fashioned operation through the perineum is not admissible.

With reference to the case just spoken of by Dr. Roberts, I believe that probably the perineal operation with curetting would have relieved the man with less after trouble. I believe that in the majority of cases where operations of this sort are done on the bladder, the tone of the bladder is so permanently destroyed that we cannot expect to restore the normal action of this organ through the natural passages. In the case Dr. Roberts has spoken of the result was all that could be desired, but I was impressed in that case, as I have been in a number of others I have witnessed, that if any man thinks it is a comparatively simple operation to go into the bladder above the pubes, he is the worst fooled man that ever took a knife in his hand. It has impressed me as being one of the most tedious, difficult and deceiving operations that a man can attempt. For my own part I do not expect to do, in my particular line of work, a great deal of this form of surgery; but, when I do it, my own preference is to go into the bladder where it is possible, through the perineum. I have no doubt that men with larger experience and with greater statistics to back them up than I am possessed of, are anxious, ready and hopeful in the matter of preference of supra-pubic cystotomy, notwithstanding the almost certainty of more or less permanent fistula which is one of the serious objections to the operation. I would always exclude the feasibility of operation through the perineum before resorting to supra-pubic cystotomy.

Dr. W. C. Dugan: I have enjoyed the paper and consider it a most excellent one in the main, but I cannot refrain from taking issue with Dr. Chenoweth in reference to the use of the rectal bag, also the use of water in distending the bladder. In the first place I do not believe that the rectal bag is of any service whatsoever in supra-pubic cystotomy, and that if the rectal bag is indicated at all, it is after the bladder has been opened. It might be well enough to insert the bag if you are operating on the prostate; or on the base of the bladder; or for tumors where you want to bring the prostate up as high as possible. There is always danger of rupturing the bladder and rectum by distension and pressure from use of the rectal bag. I think it has been demonstrated beyond a doubt that we cannot elevate the fold of the peritoneum by distending the rectum with the rectal bag. You simply push the prostate and bladder up toward the symphisis. I do not believe the bladder should be distended until after we expose the prevesical fat; it being easier in my opinion to cut down upon an empty bladder rather than upon a full one. After you have made your incision, exposing the prevesical fat, have your syringe ready and let the assistant fill the bladder with fluid and you can feel the fold of the peritoneum slip under the finger. When this sensation is felt, then have the catheter tied around the penis and the bladder opened.

While supra-pubic cystotomy is attended with considerable danger I do not think the mortality should be over five per cent. in young, healthy subjects. In old men and in patients with chronic disease of the genito-urinary passages, it must necessarily be higher.

I think the doctor's precaution of suturing the bladder to the abdominal wall by a silk ligature is an admirable one and should not be overlooked. Suturing the bladder is a very important matter if we use silk. It is difficult to get the edges so accurately brought together that the ends of the suture will not fall through. I operated upon a patient some time ago and had this misfortune to follow. A piece of the suture material dropped into the bladder through the incision, around which a calculus formed requiring a second operation.

In regard to drainage: I believe in these cases there is nothing equal to iodoform gauze. I think it is better than a tube and gives the patient much less pain. It is necessary to be very careful to have your gauze well protected and all the little threads removed, wrapped with silk so

as to be doubly sure that you are not going to leave in any of the threads to cause the formation of calculi. I do not think the operation of supra-pubic cystotomy advisable in impermeable stricture of the urethra; I have yet to see a case that could not be relieved by simple operation either by external urethrotomy without a guide, or by the perineal method. I agree with Dr. Palmer that supra-pubic cystotomy is an operation of considerable magnitude, and was somewhat surprised to hear Dr. Hunter McGuire state, at the meeting of the Southern Surgical and Gynecological Society, that the operation was as simple as the opening of a boil; I am sure he made a mistake in that. At any rate it does not appear so to me. It is an operation which requires an accurate anatomical knowledge and perfect surgical technique.

Dr. W. L. Rodman: I am very much disposed to accept the steps of supra-pubic cystotomy as given by Dr. Chenoweth as being the proper ones. I believe that in the majority of cases it is better to use the rectal bag. It has been demonstrated that you lift the peritoneum and bladder higher by use of the bag than you can possibly do without it. I believe that the danger in using the rectal bag has been over estimated. It seems to me that it is a very weak bladder that is going to be ruptured by use of the rectal bag. I have always used the bag and shall continue to do so in every instance. Instead of ligatures I use two tenacula to bring the bladder well into view, and think this is the ideal way of lifting the bladder up into the abdominal wound. I do not like the use of ligatures for this purpose; they tear out and do more damage to the bladder wall than do tenacula properly used. Their introduction is also more tedious. I agree with Dr. Roberts in regard to hemorrhage; it nearly always ceases as soon as you have opened the bladder.

I further agree with the essayist in the position taken concerning supra-pubic cystotomy for so-called impermeable stricture. It occurs to me that supra-pubic cystotomy, while not an easy operation by any means, is both easier and safer than perineal section without a guide. I have a case now that I propose to do a supra-pubic cystotomy on next Wednesday or Thursday. It is a case of impermeable stricture that I have tried to enter twice and, rather than do a perineal section without a guide, I shall perform supra-pubic cystotomy. I am very frank to say, however, that I have never in my life failed to get into the bladder through the urethra when the patient was put under chloroform. After putting the patient just mentioned under the influence of chloroform, if I fail to enter the bladder through the urethra, then the supra-pubic operation will be resorted to.

Dr. H. H. Grant: I was very much surprised to hear Dr. Dugan begin his discussion by stating that supra-pubic cystotomy was so simple as to be readily done without the use of any artificial means to raise the bladder up; afterward to state that the mortality was only five per cent, and then to criticise Dr. Hunter McGuire for teaching medical students concerning an operation as serious and grave as this one is. I think it is a very serious matter for surgeons of reputation and ability to educate young men to believe that any surgical operation can be done without great danger, or without considerable skill at the best to avoid this danger; that every means possible to make it easier and safer should be employed: and that no methods, which have received the approval and support of experienced and competent surgeons, should be discarded or condemned without some definite reason therefor.

I am firmly persuaded that in all operations of supra-pubic cystotomy that I have witnessed, and there have been quite a number, without the bag the peritoneum has appeared in the wound. I am also convinced that it is rarely seen where these means are employed.

A little difference is always to be found in the resistance of the tissues of the live and the dead body. The majority of experiments which have been employed to determine how far the peritoneum could be pushed up have been upon the dead body. Ability to push up the peritoneum and bladder by artificial means experience has shown to be very considerable, and, in many cases, the peritoneum has been found to be pushed three inches above the pubis —so far that there is no possibility of injuring it in the first incision—and easily pressed out of the way by the finger without any fear of wounding it. Certainly no danger can be experienced in distending the rectum with eight ounces of fluid in a rubber bag. When the plane which sup-

ports the prostate and the rectal base of the bladder has been raised toward the level of the pubic arch by distension of the rectum, the peritoneum will be proportionately higher as a matter of simple mechanics, and when the bladder is afterward filled with the solution the fold of peritoneum rises much more readily.

Dr. W. C. Dugan: Right at this point I would like to ask the speaker if he believes that eight ounces of fluid in a rubber bag will lift the bladder up three inches?

Dr. H. H. Grant: I have already stated that in all the operations I have seen, and there have been more than a dozen of them, in which the rectal bag was used, the peritoneum did not appear in the wound. If the peritoneum is not pushed up three inches, it is certainly pushed up some. And with this precaution the peritoneum has not appeared in the wound where the rectal bag was properly distended and the bladder was distended afterward. Upon the dead subject I have done this operation over one hundred times, and occasionally the peritoneum would be encountered. In a few instances it dropped down quite upon the pubis; but in these cases it was not pushed up either by distension of the bladder or distension of the rectum.

Of course in my remarks I simply refer to my experience, and my observation is coroborative of the wisdom of taking all means to prevent any possible wounding of the peritoneum, which is almost certainly a fatal accident unless the peritoneum be promptly closed up without any chance of infection. I look upon the operation, proper care being taken, as one comparatively easy to do. I look upon it as even less attended by risk than the operation which Dr. Palmer prefers, so far as the operation itself is concerned.

With respect to the hemorrhage which occurs after this operation, so far as the simple operation is concerned, I agree with Dr. Roberts that it is rarely troublesome. In operations upon the bladder for the removal of tumors, and especially in prostatic troubles, the danger of hemorrhage is very considerable, and it has been the practice of some to cauterize the bladder with the hot iron or thermo-cautery A safer step is to tampon the bladder with gauze fixed by a thread drawn out through a perineal wound or through the urethra as suggested by Keyes. There are a number of points with respect to the management of this operation presented in the paper that meet my approval thoroughly. It should be the object of every surgeon to avoid injury to the peritoneum in operations of this character, and I believe we ought to employ every possible means in order to prevent injury. The details of the technique which Dr. Chenoweth has given us are both interesting and adequate; are much upon the original modifications by Petersen and, having stood the test of time, are to be relied on.

Dr. W. C. Dugan: I am a little surprised at the position taken by Dr. Grant in reference to my former remarks. I did not mean to criticise Dr. Hunter McGuire, except in as far as his statement that "supra-pubic cystotomy is as simple as opening a boil." I agree with Dr. Palmer that it was an operation of considerable magnitude. Now the point I wished to make was, the best means of avoiding the dangers in this operation were by taking the precautions which I have mentioned, i. e., not to distend the bladder until you expose the prevesical fat, and then in order to locate the peritoneum after the bladder is exposed. If you will follow the precaution now being practiced by the best surgeons in America and Europe, there will be no danger of wounding the peritoneum; that is, to first distend the bladder, then slip your fingers well down toward the neck, lifting the bladder up into the palm of your hand until you feel the fold of the peritoneum slip above, then the bladder can be incised without danger.

One other point: I am greatly surprised to hear Dr. Grant state that he can lift the peritoneum three inches by an eight ounce rectal bag. I think experiments have proven pretty clearly that the bladder can be distended with water and afterward distend the rectum and it simply forces the prostate forward but does not perceptibly increase the space between the fold of the peritoneum and the symphisis.

Dr. A. M. Cartledge: It has been my observation that whenever a new operation comes up in surgery everybody is writing upon its technique, etc. After a while it dies down, and all the time it is being subjected to the crucial tests of experience and practice. After a year or two you will find some of the most interesting points concerning it have never been

brought up. I think this is notably the case with supra-pubic cystotomy. It was largely written upon a year or two ago, but I have hardly seen it mentioned within the last eighteen months. I perfectly agree with almost everything Dr. Chenoweth has said in reference to the operation. I have myself paid considerable attention to the matter, have done several operations, and witnessed others. I do not quite agree with the essayist with reference to the use of the rectal bag. I believe, like Dr. Dugan, that the rectal bag cannot raise the peritoneal fold proper more than one-quarter of an inch. If this were the case there would be danger of rupture. I have never used the bag as I never considered it of any service. Further, the rectum is the seat of a plentiful nerve distribution. I think it was proven several years ago that often very alarming syncope resulted from simple distension of the rectum by the speculum, and I see no reason why anything that would distend the rectum might not produce the same result. I think it would probably be the most dangerous part of the operation to tightly distend the rectum, even with a soft rubber bag.

I believe that a free incision should be made over the bladder, the prevesical fat and peritoneum can be peeled up from the bladder with the fingers until everything is out of the way, then the necessary incision can be made in the bladder for removing any growth or stone that may be found. I think the supra-pubic operation preferable to the perineal method for impermeable stricture; in fact, in my opinion the perineal operation without a guide is a most dangerous procedure, and useful only as a life-saving measure in the cases of larged prostate of the old.

Dr. Jas. S. Chenoweth: I use Petersen's bag in these operations because I believe better results can be obtained with it than with any other. I recommend the use of the rectal bag to raise the peritoneum, but more especially to raise and steady the base of the bladder which greatly facilitates operation on this organ.

I am sorry there was no more discussion upon the question of drainage, and whether the bladder should be fastened to the abdominal wall or dropped back into the pelvis. In most of the operations I have seen, the custom has been to simply open the bladder, remove the stone or growth, and then allow the viscus to drop back into the cavity of the pelvis. This necessitates the use of a tube for drainage, which is liable to leave a small discharging sinus after the operation; especially is this the case when the operation is done for cystitis from enlarged prostate, where the obstruction at the bladder neck cannot be thoroughly removed.

Preventive and Curative Drinks and Medicines.

Put not your trust in nostrums; cholera does not "come by Providence and go by medicine," although that is a common and ignorant belief in respect to it, and many other diseases. A tried and safe preventive of the tendency to diarrhœa (which should always be checked) is sulphuric acid lemonade, made by acidulating boiled and sweetened water to taste with dilute sulphuric acid (or, as at the post-office, Dr. Waller Lewis's very palatable sulphuric orangeade.) The citric acid lemonade lately vaunted was rather inferior in value to this. The cholera bacillus, as we now know, was favored by an alkaline fluid, and did not live in acid media. An excellent and well tried preventive of the prevalent slight diarrhœa was the Vienna mixture (used in barrels formerly in hospital practice.) It consisted essentially of fifteen drops of dilute sulphuric acid to six ounces of boiled and sweetened water, to which might be added, under medical advice, ten drops of sulphuric ether and five drops of laudanum for an adult. On ice-bags, camphor solutions, and other expedients of the kind no reliance could be placed, except in skilled hands and for selected cases. Many people poisoned themselves with camphor during a late epidemie, as a precaution against cholera. Once established, and in well-marked cases of Asiatic cholera, drugs would do little to cure. The mortality of cholera all over the world and in all epidemics had defied drugs—just as severe arsenical poisoning would do—and varied according to intensity and the age and condition of the patient from forty-five to sixty-four per cent. It was eminently a case in which prevention was far more efficacious than cure.—*Ernest Hart.*

Manager. "What's the row?"

Assistant. "The two-headed boy is quarrelling over a piece of pie."

CORRESPONDENCE.

NEW YORK LETTER.*

At a recent meeting of the Practitioners Society of New York, held at the Academy of Medicine, a discussion took place between the prominent physicians present on the question of food in continued fevers. The question was of importance as it is the general belief among the profession that solid food should not be given, particularly in typhoid fever.

Dr. A. H. Smith said that he believed he had often prolonged cases of typhoid by restricting his patient to a milk diet, and that he had often noticed a decided improvement as soon as solid foods were given. He thought that fermenting and irritating drinks, so frequently given, had a more deleterious effect upon the ulcerated patches than had solid food; that solids were not in a condition upon reaching the ileum to irritate a typhoid ulcer, and that milk dilutes digestive fluids and renders them inferior as solvents.

Dr. J. W. Roosevelt said that a prolonged milk diet prolonged a fever. He mentioned cases in which the cessation of a milk diet, and the giving of stale bread and finely chopped meat, gave marked good results; a patient on a fluid diet is hungry, and hunger is pain; the giving of solids, and consequent relief of this pain, lowers the temperature which is kept up by the pain. Professor Beverly Robinson brought up the point that milk curdles in the stomach, hence part of it becomes solid; and this solid is more apt to irritate typhoid ulcers than would such foods as bouillon, beaten egg, and wine jelly, as they are not solid upon reaching the ulcers.

Dr. Robert Abbe feeds his typhoid patients peptonized milk, junket, scraped meat, baked potatoes and stale bread. He said that none of these were any more solid upon reaching the seat of the ulcers than would be milk.

Dr. W. H. Polk said that a few years ago it was the custom to keep laparotomy patients upon an exclusive milk diet for two days before and for ten days after the operation, and that many fatal cases, attributed to sepsis and shock, were due to inaction. He has noticed a decided falling off in the death-rate since this custom has been abandoned.

* * *

At a recent clinical lecture in Bellevue Hospital, Professor H. M. Biggs strongly contradicted the teachings of most pathologists regarding the etiology of diabetes mellitus. He said that the malady was in no way due to any diseased condition of the liver; that a pathological liver may cause glycosuria, but that this was in no way related to diabetes mellitis. He gave as it's cause a brain lesion from traumatism, or mental anxiety, grief, sudden fright, or mental shock of any kind. He said that heredity was a prominent predisposing cause, and that he has often noticed several cases among members of the same family.

* * *

Professor W. T. Lusk performed symphysiotomy on a patient at the Emergency Hospital a few days ago. The woman had been in labor thirty hours when brought to the hospital. An attempt had been made by an outside physician to deliver the child with forceps, which resulted in severe lacerations of the vagina and cervix. The degree of pelvic contraction was such as to forbid any attempt to deliver the child without the operation. As the condition of the mother would not permit of the severe mutilation necessitated by Cæsarian section, the choice lay between craniotomy and symphysiotomy. The latter was chosen as it presented the advantage of the delivery of a living child and involved the mother in less risk from sepsis. After the pubes were shaved and rendered aseptic, an incision was made through the mons veneris and the sympyhsis divided from below upward. Assistants held the sides of the pelvis, not allowing a separation of the pubic bones of more than an inch, thus avoiding damage of the sacro-iliac synchondrosis and the pelvic viscera. The child was then delivered by the forceps. The pubes were brought together and held in place by sutures through the soft parts and a tight bandage

* Special Correspondent to The Medical and Surgical Reporter.

around the pelvis. At the present writing the child is doing well and the mother is living. But the length of time she was in labor, the severe lacerations she received before admission and her critical condition when an operation was decided upon, give her but slight chance for recovery.

***

Dr. L. A. Sayre, in a recent lecture, stated that he had exsected seventy-three hip joints. The operation is done much less frequently than a few years ago, as modern physicians are able to diagnose and properly treat hip-joint disease in its incipient stage. The venerable professor exhibited at the lecture a dozen patients on whom he had performed the operation. Most of them walked without any inconvenience and without the use of a cane or crutch; call were able to run up and down stairs and to do their work as well as any. A patient on whom he operated several years ago and removed the head of the femur and upper three inches of the shaft, recently won a prize in a skating contest held in Central Park. He said that the good results were due to the care he exercised in the preservation of the periosteum from which new bone developed and replaced the removed tissue.

***

Although the present epidemic of typhus fever is on the decline, new cases and deaths are reported every day. At present there are about thirty-five infected buildings in the city, many of which are cheap lodging houses. Cases when discovered are at once transferred to Bellevue Hospital, where they are kept out-of-doors in carefully constructed and well heated tents until their removal to North Brothers Island. The tent plan not only lessens the liability of the extension of the infection to the hospital patients, but is a sanitary measure proven to yield good results in any specific fever. There is no danger of the patient catching cold if he is not subjected to a draught; his temperature is lowered, and the poison is diluted as it cannot be in a hospital-ward or sick-room. The treatment has been to reduce the temperature, relieve restlessness, make the patient comfortable and promote nutrition. The death-rate has been about twenty-five per cent.

Cantani claims that no other agent equals tannic acid in the treatment of cholera.

Treatment of Compound Fracture.

A writer in the *Boston Medical and Surgical Journal* says that the treatment of compound fractures, during the past few years, has undergone radical changes and marked improvement, which has been brought about by two causes: (1) Thorough exploration and cleansing of the wound and antisepsis. (2) By the recognition of the importance of the physiological principle of complete rest to a fractured bone. The results from older methods in Guy's Hospital in the twenty years from 1841 to 1861, was a mortality of 28 per cent.; in the New York Hospital during a similar period there was a mortality of 48 per cent.; in the Obuchow Hospital Report of St. Petersburg there was a mortality of 68 per cent. Under modern methods Dennis reports 681 cases of compound fracture with one death from sepsis, giving a death rate of one-seventh of one per cent. The important points to be observed are: (1) That every compound fracture of the thigh, leg, arm or forearm, should be rendered scrupulously surgically clean and should be absolutely immobilized. (2) That this immobilization is conveniently obtained by the light, circular plaster of Paris washed bandage. (3) That a plaster of Paris bandage should be allowed to remain on a limb over a fortnight in the first month of treatment of a compound fracture, as backward bowing and lateral displacement can be avoided by this precaution. (4) That while pus, slough, necrosis or deformity may exceptionally occur, yet the rule is, union by first intention, and the early restoration of limbs to usefulness.

Treatment of Ringworm.

Crawford Warren, F. R. C. S. I., in the *London Lancet*, suggests the following treatment for this troublesome affection:

The affected region should first be washed with soap and warm water containing a little carbonate of soda and then well dried. Acetic acid should then be thoroughly applied with a small brush, and in the lapse of about five minutes, when the acid will have soaked into the part, an ointment composed of sixty grains of chrysophanic acid to an ounce of lanoline should be rubbed in. This treatment should be carried out daily for such a period as may be necessary.—*Prac. Mon.*

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JANUARY 28TH, 1893.

EDITORIAL.

ABDOMINAL SURGERY—ITS REVOLUTION.

In the *Indiana Medical Journal* for December there appeared an article by an eminent western surgeon entitled "Abdominal Surgery—Its Evolution and Involution."

This article is remarkable more for what it insinuates than for what it says. While it is strong in many respects and offers plenty of food for thought, its animus seems to be a desire to smirch the private character of Lawson Tait and to belittle his work. It is an effort to create the impression that he and men who like him publish a low mortality in their abdominal work are, if not downright liars, at least remarkable for handling the truth with a great deal of economy.

Mr Tait's work and character have so long been open to the inspection and scrutiny of the whole medical world, his reports have been so often verified, and his results duplicated by his pupils and others in this country that any attempt at the hands of an American operator to belittle him is likely to create suspicion that somebody has a grievance.

When an operator demands that hereafter all who publish low mortalities shall be compelled to furnish affidavits and certificates that their statistics are true, it begins to look as though he might be measuring others by standards applicable to himself. Such a method of reasoning is a very fallacious one indeed. The fact that those men who publish results in abdominal work with a mortality as low as three per cent. invite the closest inspection of their work and have their operating rooms daily crowded with visiting physicians from all parts of the country, is a complete refutation of any insinuation that tin-horn blowing constitutes the chief element in their success and that falsehood predominates in what they publish. There are too many honest, earnest and closely scrutinizing physicians visiting and studying these men, who write up what they see, and that only from a laudable desire to spread the truth for the benefit of others who seek information; and who expect their patients to profit by what they gain in knowledge—there are too many jealous

observers for accusations like those which permeate the article under consideration, to prove other than boomerangs to the accuser.

If the surgeon who wrote this article will spend a little more of his next vacation in Philadelphia and less in Vienna, he can have an opportunity to see just such work as that described by a number of men whom he dubs sycophants. Then, if he be the well-spring of truth his article would lead us to infer he claims to be, he can go home, and if *he* publishes anything of what he sees, it will be couched in a far different spirit than that revealed by the evolution and involution of his late effort. He will at least be enabled to recognize the truth when it confronts him in the King's Highway.

It was Lawson Tait who revolutionized the surgery of the abdomen, and who taught us that it was not the *going into* the peritoneal cavity that produced disaster so much as the *manner* in which it was done and *what one took in with him.* His saying that he would as soon put his finger into the peritoneal cavity as into his pocket was no idle boast, but came from an honest conviction born of an experience in more than three thousand sections.

Whenever another man has added to modern surgery as many things as Tait, and has taught the surgical world as much; whenever one arises to whom suffering woman owes so much; then, and not till then, may he brand Tait a liar, if he be willing to confess ignorance as extensive and principle as unstable as the three thousand miles of water between him and the traduced.

"HOUSE" QUARANTINE.

Last week we noted the passage by the United States Senate of a National quarantine measure, which poor as it was, seemed to offer some hope of protection against foreign invasion by armies of cholera microbes. This measure, crippled as it was by passing through the mill of practical politics, was sent to the House. Whence, after the skillful and patriotic treatment at the hands of Tammany scientists in consultation with experts from Florida, Louisiana and Texas, it emerges totally emasculated. The bill as sent from the Senate was amended in the House to prevent it in any way restricting, relaxing, modifying or suspending State or municipal quarantine regulations. The elimination of this objectionable feature was accomplished by citizen Bourke Cochran, of Tammany (formerly called New York State), who discovered in it the thinly disguised intention to make the Federal authority superior to that possessed by the appointee of his liege master, His Majesty, the Dictator of Tammany Hall.

As suggested by a Representative from another State, the title should be amended so as to read "A bill authorizing the States to declare quarantine against the United States." This measure should become a law immediately, so as to permit the Burgess of any little town on the sea coast, or on a State line, to defy Federal regulations, and enforce its own effective municipal laws.

It is curious to note how the same object appears viewed from opposite sides. The legend tells us of the two knights who engaged in mortal combat over the composition of the shield, of which each had seen only one side. In this part of the country there is a growing belief that the opposition to a Federal Quarantine was largely aided and abetted by an alleged steamship and railroad combination, whose interests it would seem to have antagonized. From the point of view

of a Texas medical contemporary of undoubted honesty and ability, the bill appears to be *supported* by this same alleged lobby of steamship and railroad companies in their own interests. Thus it is that whether in support of, or opposed to this measure, the steamship and railroad companies are very considerable factors in the question. This bill will now go back to the Senate, and if it is received as an original House bill (and it surely is original enough), it may be amended sufficiently to make its meaning diametrically different, and then be considered by a conference committee. The results of this last combination will be awaited with curiosity by the Profession which, in event of an epidemic, will bear the heaviest portion of the wearisome burden, and will be made the popular scape goat for the sins of omission and commission of the Representatives of the people.

TRANSLATIONS.

RUPTURE OF THE UTERUS.*

H. Fehling, (*Klin. Vortr. N. F.*, No. 54.)

The author presents the history of a case as the foundation of his dissertation on this subject.

The case a II—para of thirty-six years, having a contracted pelvis (Conjugata vera 7.5–7.7). The first child had been small and was born spontaneously. The author saw the patient first during her second labor after a spontaneous rupture of the uturus had taken place in the anterior and lower portion of the uterine wall. Delivery was at once performed by perforation and dilatation, and the treatment consisted of passing a tampon of iodoform gauze through the vagina into the uterine opening. The size of the tear, its possible septic condition due to the blood and meconium, the persistent hemorrhage all induced the author to resort to abdominal section in order to unite the tears in the uterus. Careful investigation disclosed a second tear in the uterus; both were closed by several rows of sutures; drainage and recovery. In connection with this case F. considers the causes of uterine rupture, its symptoms and treatment.

In threatening rupture of the uterus he advises the use of chloroform and morphia as a means to reduce the too active contractions of the uterus and if possible to terminate labor by forceps or perforation. In transverse positions the obstetrician will find it necessary to first attempt, under complete anesthesia, careful version. If tetanic contractions of the uterus remain unabated, decapitation is indicated. If the rupture has taken place, prompt and careful delivery is indicated in which perforation or cephalothrypsia may become necessary. It is rarely possible to extract the fœtus by its feet through the tear. Version is in all cases of existing rupture contra-indicated. If the child has escaped entire or partially through the tear into the abdominal cavity, the only proper procedure is laporotomy in order to deliver the child and at the same time repair the injuries to the uterus. If the tears are extensive or if they should be circular, partially separating the uterus from the cervix, Porro's operation is indicated.

The question which is presented at the present time, namely, should laparotomy be the first step in the treatment of rupture of the uterus, even though the child has been extracted per vias naturales, is answered by the author in the affirmative, provided the condition of the patient will permit so grave a procedure.

If section is decided upon, the author's mode of procedure is as follows: After opening the abdominal cavity, it is first cleansed of the blood and amniotic fluid, etc., by means of the physiological solution of salt. The uterus is then raised, the wound disinfected, and an iodoformized strip of gauze passed through the wound and allowed to extend out through the vagina. The wound is now closed with three rows of sutures, respectively uniting

* Translated for The Medical and Surgical Reporter, by Marie B. Werner, M. D.

the decidual, muscular, and serous layers; if necessary, some superficial stitches are added; after again cleansing the abdominal cavity thoroughly the abdominal wound is closed. The iodoform gauze is removed from the vagina after twenty-four hours.

In cases where incomplete rupture has taken place, where the peritoneal covering is intact the iodoform gauze tampon into the uterus is advocated by the author, a procedure which the author preferred to the use of a rubber drain. The gauze in these cases is not removed until from the sixth to the tenth day.

Formerly more than three-fourths of the patients died as a result from this injury.

F. believes that careful suturing of the uterine wound will improve the prognosis in these cases, the same as that of Cæsarean section, since Sænger's method of suturing of the uterus has become recognized and practical.

CONTRIBUTIONS TO THE PATHOLOGY AND SURGICAL THERAPY OF CHRONIC DISEASES OF THF CŒCUM.*

F. Salzer (*Archiv. of Klinische Chirurg.*, XLIII page 101). The material used in this study has been taken from Billroth's clinic and covers a space of ten years. During this time there were twenty-five operations on twenty-three patients for chronic inflammations of the cœcum. A fistula resulting in one of the cases necessitated a second operation. The other case was a resection of the intestine for carcinoma. A return of this disease made it necessary to perform Ileocolostomy.

Among the twenty-three patients, fifteen were males and eight females.

Ten were resections for carcinoma (eight males and two females). There were four recoveries (two males, and two females). Five operations were for tuberculous ulcerations and stenoses of the intestines at the cœcum—(five males, one female). Of these there were four recoveries (three males, one female). Eight operations for fecal fistula (three males, five females). Of the five females, three recovered. Two males recovered from the operation, one of which however required a second operation owing to the presence of a fecal fistula. The third male required a resection of the colon which ended fatally. The mortality of non-malignant tumors was twenty per cent. That of malignant tumors sixty per cent. That of fecal fistulæ 57.5 per cent. The mortality was higher among men (50 per cent.) because they were seen too late, while that of the women was 22.2 per cent. Alarming intestinal symptoms existed in three cases at the time of operation. The difficulty in diagnosing between tubercular and carcinomatous growths in the appendix is very great, the microscopical investigations being the only reliable means. Of the operations there were four intestinal sutures including one lateral suture; eighteen intestinal resections, and three intestinal anastomoses. In regard to the resection of the intestines the author believes that the simple transverse section of intestines with a circular suture can be recommended also for the resection of the cœcum, with this exception, that owing to the difference in the lumen of the cut ends of the intestines at this location one would have to be cut a little diagonally. If the tumor has become fixed by the fistulæ and perityphlitic abscesses the mode of operating as well as the prognosis becomes changed. Of the whole of the eight fecal fistulæ only one was thoroughly cured, four returned and three died, while of the seventeen other cases ten were cured and seven died. The author does not approve of intraperitoneal tampons or drainage.

* Translated for The Medical and Surgical Reporter, by Marie B. Werner, M. D.

Traveler.—"Do you think the lynch law you have here decreases the number of murders?"

Native.—"Wall, I dunno; but it decreases the number of murderers."

"If you don't stop smoking in office hours, you'll get fired, that's all," said Wagg to his bookkeeper.

"Is that quite just to one who does his work faithfully?" asked the scribe.

"Certainly. Where there is so much smoke, there must be fire."

Ischio-Pubeotomy, or the Operation of Farabeuf.*

This new obstetric operation is described by Pinard in a communication to the Academy of Medicine of Paris. He employed it in the case of a woman thirty-two years of age, who presented herself to him with an oblique pelvis associated with an ankylosis of the left sacro-iliac articulation. Her first pregnancy had been terminated by means of basiotripsy; the second by premature labor at the eighth month; the third was an instrumental labor resulting in the death of the fetus, and almost that of the mother; the fourth was terminated by premature delivery of a dead child; and finally she came in November, 1892, again pregnant and expressing the wish to be delivered of a living child. At first it was decided to perform symphyseotomy, but the existence of the sacro-iliac ankylosis led to the belief that the gain following the operation would probably be insufficient, and it would be impossible by it to sensibly increase the dimensions of the antero-posterior diameter, which was reduced to eight centimeters and a-half. Cæsarean section appearing to offer but slight chances for the mother's recovery, the operation of ischio-pubeotomy was decided upon. According to Farabeuf, the originator of the method, this operation will permit of the passage of a head much larger than the normal, nearly a sixth larger. The technique was as follows: Labor having lasted fourteen hours the ichio-pubic ramus was divided and then the horizontal branch of the pubis on the ankylosed side five centimeters from the median line. The Tarnier forceps were then applied at the superior strait and with scarcely any traction a living infant weighing 3,970 grammes was delivered. During the traction upon the forceps there was a spontaneous separation of the two severed segments of 2.6 centimeters, and, at a given moment, of four centimeters.

The sole difficulty of the operation consists in passing the chain-saw with which to cut the horizontal branch of the pubis. With a suitable needle this difficulty disappears. Hemorrhage is almost nothing. After delivery the bony fragments come in contact and sutures for this purpose are unnecessary; the soft parts must be sutured. The after treatment is very simple.—*Le Bulletin Mèdical, Jan. 11, 1892.*

* Translated for The Medical and Surgical Reporter, by W. A. N. Dorland, M. D.

Fatal Suppuration Beneath the Shoulder-Blade.*

F. A. Treskin, (*Med. Rundschau*, 1890) Suppuration beneath the shoulder-blade is of rare occurrence, indeed, so rare that the author after searching numberless text books in the German and French Literature, was unable to find any mention made of it, except a slight allusion to it in Hyetl's Anatomy.

The case which he reports was as follows:—The patient, a marine, was admitted the 29th of July, into the Lazaretto, with symptoms of acute fever, sensations of heat and cold, headache, etc. There was present diarrhœa and the thermometer registered 38.8, and in the evening, rose to 39.5. The following day acute pains appeared in the right arm, the patient coughed, the axillary glands were swollen and painful and there was some bronchial breathing. On the fourth day the entire right side, beginning from the median line in the back was swollen. At the point where the swelling was most reddened an exploratory incision was made down as far as the ribs. There was no pus present, only a slight discharge of bloody serum. Fluctuation could not be demonstrated. Anthrax was thought of, yet the microscopical examination did not corroborate it. The temperature now became sub-febrile, the pulse became slower until the fifteenth day when the patient died.

In closing Treskin lays stress upon the difficulty of the diagnosis and presents the illness as one of great gravity, particularly when the abscess lies in the deeper structures.

* Translated for The Medical and Surgical Reporter, by Marie B. Werner, M. D.

Little Bessie had been taken in to see her new brother for the first time. "Do you think you will like him, Bessie?" asked her father.

"Why, yes," she said, clapping her hands delightedly. "There isn't any sawdust about him at all, is there? He's a real meat baby."

ABSTRACTS.

RELATION OF RHEUMATISM AND CHOREA.

Dr. Townsend (*Archives of Pediatrics*) in discussing this subject before the *American Pediatric Society*, says:—"Whatever the exact relations of chorea and rheumatism may be, it seems to me that a study of cases like these teach us the very practical lesson that in a choreic child we should be wide-awake to any indefinite pain as evidence of rheumatism, and should treat it accordingly, and that we should be particularly watchful for endocarditis."

As a summary he offers the following deductions.

1st. Fright, eye-strain, debility, and school-pressure, particularly the latter, which often include some of the former, are potent exciting causes of chorea.

2nd. Rheumatism, although absent from the history of at least half of the choreic patients, occurs with greater frequency among the choreic than the non-choreic cases.

3rd. There is an intimate relation between chorea and rheumatism.

4th. The heart murmur so frequently found in chorea, sometimes associated with chorea and sometimes not, is in a considerable proportion of the cases due to endocarditis, and leads to organic valvular disease.

Dr. Crandall is of the opinion that the relation between rheumatism and chorea is a very close one and the question arises whether there is any chorea without rheumatism. Is there such a disease as fright chorea or hysterical chorea? I believe that there is, in the same sense that there is a rheumatic chorea. A study of the disease leads strongly to the belief that there is some underlying predisposing cause aside from rheumatism, fright, or hysteria. A dozen children have rheumatism and no chorea. The thirteenth has a mild attack of rheumatism and develops a severe chorea. The children in certain families are almost certain to have chorea if they contract rheumatism. Ten children are frightened by a dog and never have chorea; the eleventh at once develops a nervous disorder which increases in severity for two weeks and lasts for six months. A hundred children are scolded by their mothers with no perceptible results of any kind. One of my patients was scolded by a mother who had herself had chorea and at once developed an attack. That there is some predisposing neurotic element underlying all this I thoroughly believe. What it is I do not know. Not every one exposed to the bacillus of tuberculosis acquires the disease. That indefinite factor we call predisposition is lacking. Not every child suffering from rheumatism or subjected to fright has chorea. He is not predisposed to it. I should class rheumatism, fright, hysteria, excitement, pregnancy, not as all-powerful agents for the production of this disorder but rather as exciting agents for the production of a disease in subjects predisposed to it, the most universal and potent of which is rheumatism.

Dr. Adams in discussing this question presents the history of fifty cases of chorea treated at the Children's Hospital in Washington from which he draws the following conclusions.

1. That chorea is due to rheumatism in but a small percentage.
2. That the heart murmurs are hæmic in the largest number of cases.
3. That the successful treatment would seem to exclude latent or apparent rheumatism.
4. That anæmia and chlorosis are well marked in nearly all cases.
5. That nerve impoverishment is by far the most potent factor.

Dr. William Osler, in closing, says, it seems quite impossible to bring all the cases of chorea into the category of rheumatism. Our German colleagues, as you know, have not found more than sometimes ten per cent., sometimes fifteen per cent. In the large number of cases which I have analyzed, and the great proportion of them I have gone over myself with especial care with reference to the history of growing pains, in 554 cases there were only fifteen per cent. with a positive history of articular trouble. Including those with pains of any kind whatever the percentage was only twenty which comes to about the percentage given by Dr. Townsend. Unless we largely expand our con-

ception of rheumatism in children the cases which have come under my observation in Philadelphia and Baltimore, certainly the large proportion of them, there is no definite history of rheumatism, and the absence of the subcutaneous fibroid nodules which our English colleagues lay such stress upon is particularly striking. The only instances I have seen in this country have been in adults, not in children.

The only other point I would refer to is as to the really remarkable frequency of organic heart disease in the subjects of chorea. In the 110 cases from the Infirmary of Nervous Diseases in Philadelphia every one of which had had chorea two years prior to the examination, there were 54 with signs of organic heart disease existing. I do not mean 54 with heart murmurs. There are plenty of people with heart murmurs who have not heart disease, but signs of enlargement of the heart and murmurs of such a character as go only with organic valvular disease; and in more than fifty per cent. of these cases there has been no history of rheumatism.

A point referred to by Dr. Townsend is the extreme frequency of endocarditis in chorea. There is no other disease with which endocarditis is known to be so frequently associated, no other disease the post-mortem records of which show such a large proportion of endocarditis. The nature of the disease and its relationship are still doubtful, but the points which have been brought out here are of considerable interest and show I must say a larger percentage of rheumatic cases than has yet been shown in any series in this country, approaching much more to the English than to the German percentage.

HYDROCEPHALUS.

Dr. A. Jacobi in speaking of Hydrocephalus (*Archives of Pediatrics*) states that in the normal baby's head, while the fontanelles are open, you can count the pulse there better than at the radial; you can see the pulsations. But as soon as hydrocephalic effusion takes place to any extent, this pulsation of the fontanelle ceases.

In most cases, hydrocephalus, is either congenital or acquired early. When it is congenital, the brain is never fully developed, while the skull may be too large, or normal, or too small, at birth. Such a case may be the result of an embryonal inflammation, though no positive evidence of it can be found. The ependyma is often found thickened. The serum contains but little albumen, about one-tenth of a part per mille. Many such cases have been attributed to the obstruction of the aquæductus sylvii, or to that of the foramen magendie; in others they have been found normal. Inebriety and syphilis of the parents have been charged with producing congenital hydrocephalus. It is often found in numbers in the same family.

Acquired hydrocephalus is inflammatory in most cases; that appears to be proven by the condition of the serum which—very much like that of transudation and exudation—contains one per mille and much more of albumen. It is the result of interrupted circulation, for instance by the obstruction of the venar magna Galeni or the sinus recti, brought about by exudation or by tumors, or by slow circulation through chronic hyperæmia depending on general rhachitis. In a number of cases it has depended upon the presence of a tumor which has compressed a large vein, thereby giving rise to an effusion of water. In many cases, however, it is an inflammatory product, and the earlier it occurs, say during fœtal development, the more detrimental are its effects. The immature, soft, and flabby brain is compressed and injured or destroyed. I have seen a whole hemisphere wanting, the meninges being filled with absolutely nothing but water. In a number of cases the lateral ventricles are filled to such an extent that while the head is very large, the brain is atrophied, and sometimes nothing is left but a thin layer of cerebral tissue. These are the worst cases; as I said, the sooner the process begins the worse they are.

When it comes to treatment, you can do much more for those that are acquired than you can for those which commenced in fœtal

life. When the commencement was in early fœtal life there is very little brain tissue, and almost every one of such cases will slowly die. Acquired cases may be benefited, particularly when they go with rhachitis. Tincture of iodine, iodoform ointment and vesicatories have been applied over the cranium, all to no purpose; the iodide of potassium has been given without benefit, for where there is no brain there can be little response, new effusion will take place all the while, and the result of treatment is very insignificant. The same must be said of vesicatories, purgatives, and diuretics. It has been proposed to tap the brain. A number of recoveries have been reported from this practice. I cannot say that I have ever succeeded in curing one by this method, with or without the injection of iodine, which has also been proposed and practiced.

VAGINAL HYSTERECTOMY FOR CANCER WITH REPORT OF FOUR CASES.

Dr. Noble remarks that as the operation of hysterectomy is not conceded by the profession in general, to be the logical means of eradicating cancer of the uterus, too much stress cannot be laid upon the importance of reporting all cases operated upon, and the final results—whether cure or recurrence. And the *value* of the operation, should be determined by the work of the *few skilled* surgeons—who have reduced their mortality to five per cent.—rather than by the results obtained by a *great number* of surgeons, many of whom are inferior operators, if not absolutely bad ones. Vaginal hysterectomy being such a compartively new operation, sufficient time has not elapsed to place on record the remote results of any large number of cases. The statistics of certain German clinics attest a permanent cure in about forty per cent. of cases. As the laity and many also of the profession are proverbially hard to convince as to the efficacy of new operative measures—particularly when asserting the probably permanent cure of the much-dreaded cancer—it is of the utmost importance that all surgeons report all cases under their charge, and make additional reports from year to year, until it can be definitely shown that cancer of the uterus is curable. The theory of climacturic hemorrhage is, most unfortunately, still believed in by a large majority of the public, and many professionals as well. By experienced surgeons and gynecologists such hemorrhage is now acknowledged to be entirely abnormal and indicative of some gross disease of the uterus,—cancer, fibroid tumor, or hyper plastic endometritis.

Were this fact generally recognized, the first great step toward the cure of cancer of the womb would be taken, as it could be diagnosed and removed in its earliest stage,—making a cure almost certain. The following is the report of four cases operated upon by Dr. Noble—they being the only ones out of seventy-five cases which were not too far advanced for operation. Of these four cases, three of the women were multiparæ, and the other had had a single premature labor. The common history was purulent and profuse leucorrhœa, with more or less pelvic pain. The first case having small epithelioma of the cervix, was operated upon in May, 1889, cervix being amputated. In November of the same year, as the growth continued, vaginal hysterectomy was performed, allowing the ovaries to remain. Up to January 2nd, 1893 she was in robust health, and showed no symptoms of a recurrence of the disease. The second case was malignant adenoma; operation, removing uterus and ovaries, took place January 5th, 1892, and up to the present the patient's condition is satisfactory. Number three was also a case of epithelioma of the cervix. The uterus and ovaries were removed October 5th, 1892, and the present condition of patient satisfactory, although she experiences some pain caused by an exudate about the left ovarian stump. Case number four,—epithelioma of cervix—operation December 21st, 1892. The left ovary was converted into a cystoma which was ruptured in the removal; peritonitis immediately followed and death occurred on the fifth day.

* Read at a meeting of Phila. Obstet. Soc., Jan. 5th, 1893.

Dr. Carl Koller (*New York Med. Jour.*) in speaking of "The Subconjunctival Application of Cocaine in Eye Operations," states that his suggestions, made some eight years ago, as to the use of instillations of cocaine solutions to produce anæsthesia for operations on the eyeball met with general approbation, and subsequently the usefulness of cocaine in other branches of surgery was explored by other investigators. He states in part:—"Right in my first experiments with animals, and later in eye operations, I noticed the fact that by instillations of cocaine we were sure to achieve an anæsthesia of the superficial tissues only. I could scratch, or burn, or cauterize the cornea without the slightest pain, but the moment the iris prolapsed or was touched with an instrument, animals and human beings gave brisk signs of pain. In a great number of cases I succeeded in making the iris anæsthetic by beginning the instillations half an hour before the operation, but I did not succeed every time. In my visits to eye clinics of different countries I found that only in a very few of them were instillations begun a sufficient time before the operation to achieve this end. This circumstance, in my opinion, detracts from the value of cocaine anæsthesia in a great number of eye operations. The patient does not care which tissue hurts him. He says he has pain, and calls cocaine anæthesia a beautiful but delusive dream. The pain on touching the iris is especially troublesome in cataract extractions. The patient, who has been promised a painless operation and did not experience any pain in cutting the cornea, is suddenly thrown out of his illusions of a painless operation, makes sometimes a sudden jerk, and may thus endanger the success of the operation.

In squint operations one can notice every time that the patient does not feel the conjunctival cut, but does react quickly when the tendon is seized with the hook or forceps and divided.

Very soon after my first communication I began using subconjunctival injections in squint operations.

I proceed in the following way: After having rendered the conjunctiva anæsthetic by the instillation of a four per cent. solution, I insert the speculum and, by means of a mouse-toothed forceps, seize a fold of the conjunctiva over the tendon to be operated upon. The needle of a hypodermic syringe is inserted through this fold into the subconjunctival tissue as deep as possible, and a few drops of a two-per-cent. solution of cocaine are injected. For injections I use a two per cent. solution in preference to a four or five per cent. solution. I consider 0.05 (two thirds of a grain) as the utmost limit for adults that can safely be applied as an injection if the locality of injection is on the head, while on the limbs double the amount may be allowed. But I am careful to keep a good part within this limit. With a solution of two per cent., and even of one per cent., an entirely satisfactory anæsthesia can be produced if the solution is well distributed over the field of operation, and I attribute it to this use of weak solutions that I have not encountered yet any alarming accidents from the use of cocaine.

After the injection the speculum is removed from the eye and the eye is closed, so that the artificial œdema of the conjunctiva is given time to disappear, which it does in about five minutes. The disappearance may be helped by a little rubbing. If you have prepared a patient in this way, you can perform the operation without the slightest pain—whether it be tenotomy or advancement."

Peroxide of Hydrogen.

CHAS. MARCHAND REFUTES THE STATEMENT OF PROF. A. JACOBI.

My attention has been called to an article read before the "American Pediatric Society," at Boston, May 4th, 1892, by Professor A. Jacobi, M. D., and published in the December number of *The Archives of Pediatrics*. This article is entitled, "Note on Peroxide of Hydrogen," and purports to be a "warning."

The learned writer endeavors to convey the impression that, peroxide of hydrogen (medicinal) is a "nostrum," and that the manufacturer of this article is to be classed among "quacks and patent medicine vendors."

Dr. Jacobi mentions several cases of diphtheria, which having been apparently greatly relieved by the use of peroxide of hydrogen (medicinal), finally were cured under the use of lime water, as a spray and wash.

The inference drawn by the writer of the article in question is, that the peroxide was an "irritant" and had been of more harm than good.

It is not my province as a chemist to enter into a medical discussion with the learned doctor but I would like to ask if, in his opinion, a case of diphtheria can be treated successfully with lime water only, and whether in the cases he cites, it is not possible that the peroxide treatment was an important element in the recovery of these patients. I would also inquire whether the intemperate and in some instances personal allusions to myself and the preparation which I manufacture, are in all respects the outcome of professional investigation, and not the result of a desire to advertise himself by discrediting a remedy of which the therapeutic value has been proved by thousands of physicians who, though they may be "unsophisticated" from Dr. Jacobi's standpoint, are nevertheless known as eminent and honored professional men, all over the world.

The drift of this article is seemingly an attempt to prove that peroxide of hydrogen (medicinal) is injurious.

In confutation of this, I append herewith, in as concise a manner as possible, the experience of a few prominent physicians whose statements may be taken as conclusive in the sense that they are learned and talented professional men, the equals of the writer who challenges their experience after having undoubtedly read their opinions, for every word I quote here has been published, and forms a prominent part of the medical literature of the day.

In confirmation of my sincere belief that the claims made by me of the harmless character of my medicinal peroxide of hydrogen are true, I am willing to submit myself to a thorough test upon my own throat by spraying it with a twenty-five per cent. solution of Marchand's, peroxide of hydrogen (medicinal) instead of a five per cent. solution as alleged to have been used by the doctor, for the same continuous number of days mentioned by him; and if any ulceration appears, or if the repeated applications of the remedy "does give rise to actual diphtheria," as he states may be possible; then I am willing to acknowledge that he is right. This test may be made at any time with the utmost publicity.

I make this proposition in good faith from a scientific standpoint, and will expect Dr. Jacobi to make the test in the same spirit or acknowledge that he does not desire to do so.

THE LIBRARY TABLE.

A Handbook of the Diseases of the Eye, and Their Treatment. By Henry R. Swanzy, A. M., M. B., F. R. C. S. I. Fourth edition with illustrations. [Philadelphia: P. Blakiston, Son & Co., 1892.]

That the third edition of this work, published in October, 1890, should have been exhausted within two years and a fourth edition called for, is positive testimony to its value. Although it is a small book compared with many similar treatises, the information contained in it is so well selected that one reads it with satisfaction. It is not so elaborate as to be wearisome, yet it is complete enough for a guide to the general practitioner and, in many instances, is sufficient for the specialist. The work possesses a distinctive character. It is the production of a mind capable of appreciating the essentials of Ophthalmology, together with the ability to present them in a clear and forcible manner.

This fourth edition has been revised throughout and brought up to date. New means for accurate diagnosis are fully explained, and new remedial measures are described in detail.

While there is no endeavor to present a systematic account of the anatomy and physiology of the eye and its appendages, there are several interesting references to the results of recent investigations in these departments. Instances of this occur in Chapter xi, devoted to "The motions of the pupil in health and disease;" and in Chapter xviii upon "Amblyopia and amaurosis due to central and other causes." Two colored diagrams of "The course of the optic fibres, with the centres of the three visual perceptions, and relations to fields of vision," illustrate the two theories of the macular nerve supply. One is that each macula is innervated from the opposite hemisphere; and the other, that the macula is supplied on the same plan as the rest of the retina, i. e., each side from the corresponding side of the brain.

The subject of treatment of the various diseases of the eye has received careful attention throughout the book. Granular ophthalmia is referred to at considerable length, and the various methods of treatment are fully given. Squeezing out the granulations by means of Knapp's roller forceps is very favorably mentioned.

A caution is given as to the use of jequirity, the author concluding his remarks upon it by saying that "the presence of well marked pannus of the cornea

without ulceration is, I think, the only thing that can render the employment of jequirity justifiable, and, in addition to this, the conjunctiva should be free from blennorrhœa."

In the treatment of corneal ulcers he does not write very enthusiastically of the use of miotics. He considers that they increase the tendency to iritis. Referring to the modern method of thoroughly cocainizing the eye before proceeding to operate for extraction of cataract, he says, that previously to the introduction of cocaine, general anæsthesia with ether or chloroform was commonly employed in England. I never used it." He insists upon careful attention to antiseptic measures, before and during the operation. He presents a very careful description of the "*Three millimetre flap operation*" for cataract extraction in which iridectomy is performed. In his defense of this "combined method," when discussing the subject of "Cataract Extraction *without* iridectomy," he says, "whilst admitting the charm of a circular pupil, I am of the opinion that the question is not whether the appearance of the eye is pleasing to us and to those who inspect them, but rather what advantrge the greatest number of persons operated on derive from the operation. With sentimental talk about mutilation of the iris I cannot pretend to sympathize."

In an appendix Holmgren's method for testing the color sense has been described in greater detail than before.

Swanzy's Handbook bids fair long to hold its place upon the tables of our libraries.

A Manual of Clinical Ophthalmology. By Howard F. Hansell, M. D., and James H. Bell, M. D., with 120 illustrations, pp. 231. [Philadelphia; P. Blakiston, Son & Co., 1892.] Price $1.75.

The authors preface this manual by stating their purpose "to place before the undergraduate and general practitioner of medicine, a brief review of the anatomy, physiology, refraction, and common diseases of the eye." Right well have they performed their work forwe rarely meet with a book which contains so much accurate and valuable information condensed into so small a space.

The first part contains a succinct account of the general Anatomy and Physiology of the eye. This is followed by other sections on Physiological Optics, Refraction, and Ocular Muscles. The remander of the book is devoted to Diseases of the Eye and to Operations.

Although the description of each disease is concise, it is sufficient for recognition; and the treatment is shortly but emphatically given. There is no redundancy. All information is of the most practical character.

This book of 231 pages contains no less than 120 illustrations. As the authors frankly state, none of these are original, but their value has been greatly enhanced by the care which has been exercised in their selection and the excellent manner in which they have been reproduced.

To the undergraduate and general practitioner, for whom it is prepared, it will prove an excellent introduction to more exhaustive treatises on the subject. One recommendation is the low price at which it is published.

Appendicite et Perityphlite, Ch. Talamon; Pleurisies Purulentes, Debove et Courtois-Suffit; Le Rachitisme, J. Comby.

Dr. Talamon has written for the "Bibliothique-Medical Charcot Debove," an excellent monograph on "Appendicitis and Perityphlitis. He discusses the history of the observations from the case published by Negeler in 1813, to the latest histories and operations of Treves, Oppenheimer, McBurney and Keen. Melier in 1827, suggested the wisdom and possibility of operation and reported three cases of perforating appendicitis. The whole subject is discussed intelligently with a thorough knowledge of the accumulated literature of the last ten years, and a useful if perhaps too minute plan of sub-division of the various forms according to the anatomical situation of the part primarily affected is suggested. The author insists, with Ashley of Baltimore, that unrecognized appendicitis is more frequent in woman than is supposed. The activity of American surgeons in this subject is well represented by numerous citations, and Dr. Talamon gives them full credit, while disagreeing with what he thinks a too strong tendency on their part to early operation in preference to the conservative medical treatment he would follow.

Another volume of the same series on the "Treatment of Purulent Pleurises" is by Debove and Courtois-Suffit. American surgeons have not so large a share here, and indeed scarcely appear at all. The authors have not written a polemic in favor of thoracentesis or lavage, but a calm discussion of the whole subject, with insistence upon the importance before operation of careful study of the individual case, especially by means of bacteriologic examination. "When we know the variety of empyema, the nature of the pathogenic agent producing it and the virulence of this agent, we can deduce the probable course of the pleurisy; but above all we can choose the most reasonable method of interference." The study is divided under three heads, the evolution of medical ideas on the subject, the different useful operative procedures, and the methods applicable to each variety of purulent pleurisy.

The third volnme of the same series which bears the apparently necessary name of Charcot, is on "Rachitis," by Dr. Comby. This disease once fortunately uncommon among native whites in this country, is growing more frequent with the increasing pressure of our population. It is one of the maladies which has not been revolutionized by bacterial pathology, but the new interest in minute pathology and the new knowledge of the evolution, prophylaxis and treatment lends it interest. Like the other manuals already reviewed, this one is well up to the information of the day, and if on a matter of less active general moment, is none the less valuable for its clearness, simplicity and fullness.

Curious Questions in History, Literature, Art and Social Life; designed as a Manual of General Information. By S. H. Killikelly. In two volumes. Philadelphia: The Keystone Publishing Co., 1892.

This is a valuable work. Nearly 600 questions are propounded and answered. Probably not one-twentieth of these questions could be answered off-hand and correctly by the best-informed person in any ordinary community. How many readers know: "What noted warrior led his troops into battle after his death?" "What kind of a tub did Diogenes live in?" "What is the Key of Death?" "What city was destroyed by silence?" "When was ecstasy an infectious disease?" These sample questions selected at random, are answered fully, but not fulsomely.

It is a work for cultivated people, and the amount of useful information to be gained from its pages will amply reward the purchaser.

The paper is good and the type clear and legible. "Curious Questions" is bound in two styles; one in dark green cloth, the other in half morocco. The latter style is illustrated.

Medical Journal Advertising: A Manual for Advertisers. Edited by A. L. Hummel, M. D. Price one dollar. Published by Hummel & Parmele, 612 Drexel Building, Philadelphia, 1892.

Intending advertisers will find much of value, and all will be interested, in this book. A number of men, prominent in medical circles, contribute articles of real value. It is an educating book in the sense of showing the benefits of advertising, and in teaching the advertiser how to word and place his announcements to the best advantage.

CURRENT LITERATURE REVIEWED.

PACIFIC MEDICAL JOURNAL.

Dr. Fred. W. D'Evelyn contributes a paper on "The Right Heart in Circulatory Obstruction," in which he cautions against the use of digitalis and its fellows in those cases where the right heart is engorged, and the left side really depleted through the venous engorgement and lack of arterial blood.

Dr. A. W. Perry, in his article on the "Surgical Treatment of Puerperal Endometritis," advises the use of the curette followed by an antiseptic douche in puerperal sepsis, especially those cases where there may be retained portions of placenta or membranes.

The number concludes with an account of "Receiving Hospital of San Francisco," by Dr. Tenison Deane. The hospital is under the charge of the Board of Health, and has accomodations for about twenty patients besides a ward for alcoholic cases. A surgeon is constantly in attendance; fractures are treated; fractured skulls are trephined; laparotomy is done for stab and gunshot wounds, "In fact every conceivable injury is treated at the hospital during the year."

VIRGINIA MEDICAL MONTHLY.

Dr. J. M. Baldy's article on "Uterine Fibromata" gives his experience in hysterectomy. He has removed twenty-seven tumors with two deaths. He pursues the supravaginal extra-peritoneal method, and commends that as being the most uniformly successful.

Dr. John Dunn reports two cases of "Congential Chorea." Dr. N. L. Guice reports a case of "One-sided Swelling of the Face," as the result of malaria.

Dr. William C. Dabney contributes a clinical lecture on "Valvular Disease of the Heart," and defines the indications for digitalis in such cases. There is also a report of a "Aneurism of the ascending arch of the Aorta," by Dr. Llewellyn Eliot. "Dysentery, Its Prevalence and Treatment," is the title of a paper by Dr. L. Ashton. Dr. George Corrie describes an improved "Urethrotome," made after the well known Otis instrument, but differing from it in having a bulb at the distal end of the upper bar of the shaft, which, Dr. Corrie claims, besides sheathing the knife, "defines the tissue to be cut, avoiding the annoyance and uncertainty of having to take measurements." There is also an indicator attached which shows accurately the movements of the blade.

Dr. Chas. G. Cannaday advocates the use of the galvanic current, with faradization, as a "Uterine Developer," giving the report of two cases treated in this way. He claims that, by this method, the uterus is stimulated to take on new growth, the menstrual functions are restored, and dysmenorrhœa and sterility cured. [Tonics and carefully regulated hygiene are also part of the treatment and, in the minds of some, will be accredited with the improvement noted and not the electricity.—Ed.]

MONTREAL MEDICAL JOURNAL.

Dr. W. Johnson reports a case of extensive fracture of the skull as the result of a "Gunshot wound through the orbit." The report is interesting from a medico-legal point of view and Dr. Johnson gives the result of several experiments on the cadaver, made to show the injuries on the skull that would be received by the discharge of a load of shot through the orbit at close range.

Dr. Thomas R. Dupuis, in an article on "Goitre and its treatment," rejects surgical interference as likely to be followed, even if the patient survive, by cretinism and an enormous increase of mucin in the body or *myxœdema*. The various non-surgical methods of treatment are discussed and, while the disease is fortunately rare in this portion of the country, the article is worthy of attention as an addition to our knowledge of the subject.

Dr. J. A. Springle reports a case of "symphysiotomy," performed for contracted pelvis. The forceps had been applied and failed to deliver. After division of the symphisis, forceps were again applied and a living child delivered. The number also contains an address by Sir James Grant, M. D., on "Queen's University and Medical Education."

THE PHILADELPHIA POLYCLINIC.

In the January number of *The Philadelphia Polyclinic* Dr. Baer calls attention to "The Danger of Delay in Pelvic Abscess." Dr. Roberts offers a few remarks on "The Pathology and Treatment of Internal Hemorrhoids."

Dr. Contrell having witnessed many mistakes in the diagnosis of the two affections, "Psoriasis and Syphilis," presents one case of each with a study of several features which are prominent in each.

ARCHIVES OF PEDIATRICS.

The January issue of the *Archives of Pedriatics* contains an interesting discussion on "The Relation of Rheumatism and Chorea" by Dr. Townsend of Boston, Dr. Crandell of New York, and Dr. Adams of Washington, of which fuller mention is made elsewhere.

Types of Infantile Syphilis.

by Dr. Stowell, is deserving of a careful reading. In the treatment of these cases, he states that he has "fallen into a habit of using what proved good." Inunctions of oleate of mercury for infants, with mixed treatment to the mother, if nursing. Older children, especially in late manifestations, were given mercuric chloride in doses ranging from 1-120 to 1-32 of a grain according to age. Mercury we find lauded in all forms. Calomel or grey powder is easily administered, but at times proves too laxative unless checked by an opiate. Inunctions of two per cent. of oleate of mercury, or of the officinal ointment, are better than internal medication. Judicious feeding and general tonics must not be forgotten, for the evil is only removed by constant and long continued vigilance.

A clinical lecture by Dr. A. Jacobi on "Multiple Sarcoma," and "Hydrocephalus" completes the list of the more important papers. This number also contains an open letter from Mr. Marchand in protest to strictures upon Peroxide of Hydrogen made by Prof. A. Jacobi, in a former issue of this journal.

JOURNAL OF CUTANEOUS AND GENITO-URINARY DISEASES.

For January the leading article offered is a new and successful mode of treatment in "Xanthoma Tuberculatum" by Dr. Morrow. It is illustrated by a chromo-lithographic plate which is of great assistance in elucidating the subject.

Dr. Blanc reports

A Case of Skin Shedding,

in which the epidermis of the hands and feet, particularly the former, came off almost without a break, resembling gloves and moccasins. The nails were loose but did not come off at this time. The doctor believes that while, from the general character of the case, this is not a true type of *dermatitis exfoliativa*, yet it resembles it sufficiently to be a variety of it.

Dr. Hartzell has a carefully prepared paper on "Sarcoma Cutis." The subject matter is well illustrated.

THE BRITISH JOURNAL OF DERMATOLOGY.

The Journal of Dermatology for January contains but one article and that a monograph by Dr. Stephen Mackenzie, on

Dermatitis Herpetiformis

which is defined as a cutaneous neurosis characterized by the multiformity of its manifestations, which may consist of erythematous, papular, vesicular, bullous, and urticarial eruptions, which may appear concurrently or consecutively and are usually attended with pigmentation of the skin; a grouping of vesicles is the most characteristic feature, and present in most cases at some part of their course; it is usually attended with great itching and burning; it runs a chronic course with exacerbations, or relapses and intervals, and usually terminates spontaneously, but may end fatally; it is attended with some, but usually not serious, disturbance of the general health; it affects both sexes, and at all ages, but is most common in the middle period of life; in women it is often connected with pregnancy, but may occur independently of it." It is not surprising that such a polymorphic disease should have received a variety of names. The author has adopted the present name, given the disease by Dr. Duhring, which seems the most generally accepted, as it is the most descriptive.

Neuroses after Removal of Appendages.

Debove (*Nouv. Arch. d' Obstet. et de Gynec.*, 1892) demonstrated at a recent meeting of the Societe Medicale des Hospitaux that removal of the appendages may do worse than fail to cure hysteria and pelvic pain. It may fail to prevent, and may even excite, a neurosis. A woman, aged 38, had her appendages removed in December, 1889. The ovaries were found "diseased." Her period did not recur. On June 28th, 1890, she had a severe nervous attack, which recurred. Debove examined her during one of the seizures. There was right hemianæsthesia with the typical so-called ovarian pain in the iliac fossa. Thus this sympton may exist when no ovary remains. Compression over the region set up an attack, and the pain could be transferred by the application of magnetism. Desuos, in discussing the case, stated that he had twice seen insanity after ovariotomy. Rendu noted that many abdominal operations were followed by the same result. He saw insanity commence in a woman a few days after an operation for artificial anus. The mental disease proved incurable and fatal. Mathieu had seen nymphomania after removal of the ovaries.—*Br. Med. Jour.*

PERISCOPE.

THERAPEUTICS.

Dr. H. A. Hare (*Therapeutic Gazette*) recommends strychnine as a remedy for and the prevention of surgical shock, anæsthetic collapse and opium-poisoning. He states that it must be given in full doses or not all all. Not less than a twentieth of a grain should be used hypodermically every half-hour for an adult; and if the shock be marked, a dose of as much as a fifth of a grain may be given in this way. Disagreeble effects rarely follow, and will probably amount to no more than muscular twitching, which can be readily controlled by sedatives. In describing a visit to Professor Horsley's laboratory, he says that a monkey upon whom a brain experiment was being performed was placed in a water-bath and well covered to attain the proper heat. This is considered necessary for the survival of the monkey, and from it may be inferred that the application of heat about the body of a person undergoing an operation is of the greatest importance. The same is also true in cases of hemorrhage and shock. Experiments by Brunton show that animals poisoned with chloral die from doses, which, when artificial heat is given them, fail to produce dangerous symptoms.

MEDICINE.

Actinomycosis Hominis.

Dr. Justus Ohage in writing on this subject says that actinomycosis in man is one of the so-called modern diseases, that is, its recognition, description and understanding are due to modern investigation and discoveries.

The first to recognize this disease was James Israel, in Berlin, in 1878. He published his observations in Vol. 74, *Virchow's Archiv.* Ponfick, of Breslau, gave a fuller description of it in 1879, and was the first to demonstrate that the disease in man was really due to a fungus, the actinomyces first discovered in 1877 by Bollinger in the jaw of cattle. Since then numerous observations have been published and this disease has obtained full pathological recognition. Actinomycosis is more frequent in Europe than here, at least it is oftener diagnosed and recognized over there; still the disease is common enough in this country to demand the attention of the medical profession.

The disease is produced by the entrance of a vegetable parasite or fungus into the system. The raylike arrangement of its elements caused Harz to name it actinomyces, "aktis," ray, "mykis," fungus. The experimental researches of Ponfick, DeBray and Pringsheim have conclusively shown that this fungus is the true *causa morbi* of the disease in question, and have proved the identity of it in man, cattle and hogs beyond any doubt.

The diseases with which actinomycosis is most often confounded are tuberculosis and epithlial cancer. It gains its entrance into the system in various ways. The fungi may enter with various kinds of food, by inspiration, etc., and according to the channels through which they entered the system the symptoms of the disease make themselves manifest. We have thus actinomycosis of the lungs, the kidneys, the bowels, the stomach, etc.

Most cases of actinomycosis in man have their starting point in decayed teeth and diseased tonsils. From here the fungus is distributed through the organism and begins the destruction of the organs on which it has settled. The protean character of this disease is indigenous to man only, while in the lower animals, cattle and hogs, its predilection is for the jaw. There is another peculiarity—the tendency to the formation of tumors in animals is entirely absent in man. On the contrary, the granular tissues produced by the phlogogenous action of the fungus tend to fatty degeneration and decay. In an insidious and chronic manner the fungi penetrate the tissues, destroying them in their onward march, and unless the perforation of some vital organ as the stomach, or the bowels, or the lungs cuts life short, the mode of death is generally that by pyæmia.

The diagnosis of the disease during life is comparatively easy if the ravages of the fungus are visible to the eye, as in the first two cases which I shall presently describe. A peculiar form of small yellow bodies is always found in the pus, fistulæ and swellings; it is unmistakable after once having been seen. On microscopical examination they seem to consist of threads terminating in bulbous ends. The threads radiate from the centre, thus giving the fungus a ray-like appearance.

When internal organs are attached, hidden from view and inaccessible to observation, the diagnosis is impossible.

The prognosis and treatment of actinomycosis is based upon its indigenous properties. As it is a local fungus disease, not constitutional like syphilis and tuberculosis, it is curable if all the infected tissues can be removed. Where that cannot be done a fatal termination is inevitable.—*Northwestern Lancet.*

Aural Symptoms of Neurasthenia.

Dr. Suney Molist (*Annales des Mal. de l'Oreill*, Dec., '92) offers an explanation of the annoying symptoms, in the form of subjective noises, which are so prominent in many cases of neurasthenia, and which are accompanied often by a considerable diminution of the hearing by bone conduction. These cases of tinnitus are grouped by the author as follows:

(1) Simple suspense of vaso-motor inhibition of the vessels of the cochlea, which, by their pressure upon the terminations of the acoustic nerve, cause a continuous tinnitus, which may be temporarily relieved by forcible compression of the carotid.

(2) Patients who have previously had an

otitis, who are rheumatic subjects or who have an atheromatous condition of the vessels which once dilated do not readily return to their previous condition, the result of this continued dilatation being exudation into the membranous labyrinth or, possibly hemorrhage.

(3) Affection of the perceptive power of the internal ear as the result of the long continued vaso-motor disturbance; in these cases the tinnitus gradually increases in intensity, as does also the impairment of hearing, and to these two symptoms is sometimes added vertigo.

According to Rampoldi (*Annual Univ. de Med.*) there are five groups of sexual diseases which affect the eye, as follows:

(1.) Hysteria and chronic metritis are causative of asthenopia and retinal hyperæsthesia.

(2.) Menstrual disorders. Amenorrhœa is causative of conjunctivitis keratitis, iritis and phlyctenulæ. To suppression of the menses he refers diseases of the choroid, with neuritis and retinitis. The tendency to glaucoma is known to accompany a sudden suppression.

(3.) Inflammatory diseases occur in hyperæsthesia and neuralgias of the trigeminus.

(4.) Pregnancy causes the difficulty accompanying the albuminuria of that state. Amblyopia and amaurosis have been common from three to fourteen days after hemorrhage.

(5.) During lactation and the puerperium the following have been observed: Panophthalmitis, ulcers of the cornea, retinitis, photophobia, disturbances of accommodation and other morbid conditions resulting from debility.

Discriminating Diagnosis Between Cerebral Hemorrhage and Acute Softening.

CEREBRAL HEMORRHAGE.	ACUTE SOFTENING.
1. Age, thirty to fifty.	1. Earlier or later age.
2. Hereditary history of arterial disease.	
3. Sudden onset with coma and paralysis occurring together, the coma deepening.	3. Premonitory symptoms and more gradual onset or more transitory coma.
4. Stertorous breathing, and hard, rather slow pulse.	
5. Peculiar alternate conjugate deviation of the eyes.	
6. Early rigidity.	6. Rarely occurs.
7. Convulsions.	7. Seldom present.
8. Initial subnormal temperature followed by a rise in twenty-four to forty-eight hours.	8. No initial fall of temperature. But slight tendency to subsequent fever.
	9. Presence of weak heart or endocarditis. Slight hemiplegia with aphasia. The puerperal state.—Dr. Dana.

SURGERY.

Dr. Darrah (*Boston Med. and Surg. Jour.* Jan. 12, 1893) in a report of three cases of caries of the coccyx draws the following conclusions:

(1) That caries of the coccyx occurs very infrequently.

(2) That it is more common in females than males.

(3) That there are these important points in considering the diagnosis of these cases: (*a*) history of injury; (*b*) constant pain; (*c*) multiple and persistent sinuses (not always present); (*d*) that persistent sinuses should lead one to suspect caries of the coccyx; (*e*) that excision of the coccyx is the best treatment for all cases when there is disease of that bone.

The Early Extirpation of Tumors.

In a paper read before the New York State Medical Association, at its recent meeting, Prof. J. W. S. Gouley presented the following conclusions on this subject:

1. Malignant tumors exceed benign tumors in frequency.

2. That malignant tumors comprise epitheliomata, sarcomata and internal adenomata.

3. Among the benign tumors myxomata and external adenomata often recur after incision, but do not infect the system.

4. There is no solid benign tumor that may not become malignant.

5. No means are known by which can be ascertained the precise time of the beginning of metamorphic action in tumors.

6. Most malignant tumors have a stage of benignity.

7. Excision of potentially malignant tumors in the early epoch of their stage of benignity is likely to effect a permanent cure, or at least to prolong greatly the period of immunity from recurrence of the disease.

8. In the excision of malignant tumors the greatest care should be taken to remove as much of the ambient tissue, including fasciæ and lymph glands, as is compatible with good judgment.

9. General treatment of tumors has no value except as an adjuvant of a surgical operation, and is often indirectly injurious, leading the patient to expect a cure by perservering in the use of drugs, and thus allowing the disease to make rapid progress toward a fatal end.

10. Local treatment of tumors, by means of escharotic plasters, pastes or powders, is the most fruitful in evil of all the devices for the torture of the afflicted. The plaster, paste or powder causes the greater part of the tumor to slough, but there is enough left behind for the most rapid extension of the disease. The effect of the escharotic is, therefore, only to till a soil where new growths sprout like so many seeds cast upon a rich loam.

11. Compression is delusive in the case of tumors containing cysts, and is directly hurtful by exciting the rapid growth of most tumors.—*At. Med. and Surg. Jour.*

Treatment of Aortic Aneurysm by Electrolysis through Introduced Wire.

Stewart (*Amer. Jour. Med. Scien.*, October, 1892) reports a case of large sacculated aneurysm of the aorta treated by the introduction of wire and electrolysis. This treatment was tried with the object of promoting prompt formation of firm protecting coagula, in order to retard rupture of the thin-walled sac. The aneurysm, which had arisen from the lower part of the thoracic aorta, and subsequently had involved a portion of the abdominal aorta, was a very large one, and bulged backwards so as to form a prominent pulsating swelling in the left lumbar region. The patient was a man, aged 32. In his operative treatment of this case the author chose a rather heavy silver wire with the idea that the presence of large supporting spirals in the sac occupying much of the cavity, and affording a good framework for clot, would offer a better chance of immediate success than the use of a thinner and more pliant wire, which might undergo deflection from its course of introduction through coming in contact with loose coagula already in the sac. Two and a half feet of wire and also one end of a platinum needle were introduced into the sac, and a current, after being gradually increased to a strength of 70 milliamperes, was maintained at this point for one hour. The wire was passed through a canulated steel needle two and a half inches in length. The condition of both needles on withdrawal showed unquestionable clot formation about them.

On the third day from the date of operation a remarkable change was noticed in the condition of the aneurysm. The prominent pulsating portion in the left loin had become depressed, and transmitted pulsation could be detected in it. The whole of the lower part of the aneurysm felt much firmer, and was quite without pulsation, while the extreme upper part seemed to have undergone no change. The patient, however, continued to suffer severely, and, on the ninth day, died very suddenly in consequence of the rupture of the sac. At the necropsy firm clots were observed in all portions of the aneurysm, together with soft ones evidently of very recent origin. The wire was engaged in several large firm clots, which were of so solid a texture that when examined in that part of the sac which was removed they could not be separated from the sac and wire without some difficulty.

OBSTETRICS.

Asepsis and Antisepsis in the Lying-in Chamber.

Potter makes the following propositions concerning asepsis in the puerperal chamber.

1. Let us begin by making the patient as nearly clean as possible for soap and water to accomplish.

2. Let her, prior the beginning of labor, have an immersion-bath daily for several days, and with the first manifestations of pains, let her abdomen and genitalia be rendered absolutely aseptic by further application of germicides in solution, adequate to accomplish the desired end.

3. Let her have a warm vaginal douche, rendered aseptic.

4. Let the lower bowel be thoroughly evacuated by copious lavements of hot water prior to the vaginal bath.

5. Let her bedding be made as pure and clean as careful laundrying can make it.

6. Let her clothing be made equally clean in like manner.

7. Let there be a number of clean bichloride napkins placed in readinesss for use.

If all of these injunctions are rigidly enforced, we have done much to lay the foundation for a physiological labor.

The physician and all the attendants must be rendered as scrupulously asceptic as the patient herself. The nurse must be especially trained in the habit of keeping her hands clean. After the first examination, which should be made as carefully and deliberately as possible, the physician should refrain from further examination unless absolutely required.

Suckling and Quinine.

Oui (*Arch de Tocologie et de Gynec.*, December, 1892) finds that when the mother or nurse takes quinine it has no ill effect on the child. The drug is certainly excreted with the milk, but in very small quantities. The quininised milk has absolutely no influence on the child. After a series of careful weighing and measurement, it was found that the average was the same in children suckled for a given time by nurses who had taken quinine as in children whose nurses had not taken that drug. Hence a nurse or mother may safely take quinine. Burdel's theory that quinine is noxious to the child is incorrect, and the precautions which he recommends are therefore unnecessary.—*Brit. Med. Jour.*

Missed Abortion.

Liebmann, of Buda-Pesth (*Centralbl. f. Gynak.*, No. 38, 1892, from the *Arvosi Hetilap*), relates a case in which the remains of a fœtus which had died *in utero* were discharged piecemeal. A three-para suffered at the fourth month of pregnancy from a fœtid sanious discharge, which lasted for two weeks; then pieces of fœtal bone began to come away. The process took about seven months, with intervals corresponding to the greater or less strength of the uterine contractions. Some of the bones were discharged singly; some remained articulated and required forceps for their removal. The placenta came away four and a-half months after the beginning of the abortion. The number of bones that were thus gradually delivered amounted to over seventy, and indicated that the fœtus had reached the third month.—*Ex.*

GYNECOLOGY.

Fatal Rupture of Pyosalpinx: Suspected Abortion.

Rochet (*Journ. d'Accouchements*, 1892) recently described a case of rupture of a pyosalpinx from rough handling during the application of the curette to the uterine cavity. He adds a yet more instructive case. A female servant, aged 26, was admitted into hospital, losing blood. She fancied this might be due to a miscarriage at the first month, which she believed to have occurred on the previous evening. The uterus seemed normal. A tender mass of the size of a small egg, lay in Douglas's pouch. A few days later the patient insisted on leaving the hospital. She was therefore examined first; the mass was found smaller and less tender; at the time the examination caused no pain. Pyosalpinx was diagnosed, and the patient, instead of leaving the hospital, remained, and an enema with a dose of castor-oil was given in view of an operation. In the evening the patient became very ill. Next morning an exploratory operation was performed. Pus escaped freely when the abdomen was opened. Douglas's pouch was laid open and drained. The patient died in a few hours. There was a judicial inquiry owing to a suspicion that she had died from attempted abortion. There was no doubt that the cause of her death was rupture of a pyosalpinx. The uterus showed signs of recent early pregnancy. There was no evidence of criminal abortion. Rupture of a pyosalpinx is no doubt the cause of many mysterious deaths after curetting, dilatation of the uterus, etc., when the uterus is dragged downward, or pushed upward with violence.—*Brit. Med. Jour.*

ARMY AND NAVY.

FROM JANUARY 15, 1893, TO JANUARY 21, 1893.

First Lieutenant Thomas U. Raymond, Assistant Surgeon, is relieved from further duty at Vancouver Barracks, Washington, and will report in person to the commanding officer Fort Canby, Washington, for further duty at that station, relieving Captain Edward C. Carther, Assistant Surgeon, who on being thus relieved, will proceed to Vancouver Barracks, and report in person to the commanding officer of that post for duty there.

Captain Guy L. Edie, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Neobrara, Nebraska, and will repair to New York City, New York, and report in person to the attending surgeon in that city, for duty in his office.

Leave of absence for four (4) months, is granted Captain Jefferson D. Poindexter, Assistant Surgeon, U. S. Army.

NEWS AND MISCELLANY.

One of the Ways by which Corporations Reduce the Income of the Medical Profession.

In general it may be said corporation exist to reduce to the lowest possible degree the incomes of all with whom they deal. On former occasions we have called attention to the effect of railroads upon the income of surgeons. But just now we desire to call attention to the influence of accident insurance companies in diminishing the income of the profession.

Formerly when one of the employes of a manufacturing establishment was injured, either the employe called upon his own doctor or the company sent him to a well known practitioner. After recovery, either the man paid the doctor what he was able to, or the company paid the bill. In either case the doctor got a reasonable reward for his work and responsibility. Lately companies have been formed that agree for a certain sum to look after the injured employes. The results of this plan are that the accident company deliberately sets about to cheat the doctor out of his fee for service. It employs men adapted for this particular purpose. If they fail in other ways, they dump the patient into the charity ward of a hospital, paying his board and making the hospital doctor do the work for nothing. In the aggregate the money thus lost to the profession and put into the pockets of the accident insurance company is very large.

In this case we do not see any way by which this leak can be stopped, because all doctors, will not combine to prevent it. In a different form, it is the same as with the railroad doctors. All will not agree in refusing to do the work without fair compensation. In each case, if one refuses, another takes his place on the terms offered by the corporation. In the contest between doctors and corporations, the latter take the money and keep it, while they leave for the doctor all the glory.

As to the benefit to employes, the following is significant. The writer, observing a dangerous condition of a freight elevator, directed the attention of the proprietor to it. He carelessly replied that it made no difference to his house, as a casualty insurance company was paid to protect the firm from all damages.—*American Lancet*, Nov. 1892.

Popular Tours to Washington.

Personally conducted tours to Washington have been arranged via Royal Blue Line, to be run at frequent intervals from New York and Philadelphia to Washington. The next excursion will be on February 2nd. For programme describing these tours, write to Thos. Cook & Son, Agents B. & O. R. R., 261 and 1225 Broadway, New York, or 332 Washington Street, Boston.

Professor of Chemistry, N. Y.

The Demand For

a pleasant and effective liquid laxative has long existed—a laxative that would be entirely safe for physicians to prescribe for patients of all ages—even the very young, the very old, the pregnant woman, and the invalid—such a laxative as the physician could sanction for family use because its constituents were known to the profession and the remedy itself had been proven to be prompt and reliable in its action, as well as pleasant to administer and never followed by the slightest debilitation. After a careful study of the means to be employed to produce such

A Perfect Laxative

the California Fig Syrup Company manufactured, from the juice of True Alexandria Senna and an excellent combination of carminative aromatics with pure white sugar, the laxative which is now so well and favorably known under the trade name of "Syrup of Figs." With the exceptional facilities, resulting from long experience and entire devotion to the one purpose of making our product unequalled, this demand for the perfect laxative

is met by Our Method

of extracting the laxative properties of Senna without retaining the griping principle found in all other preparations or combinations of this drug. This method is known only to us, and all efforts to produce cheap imitations or substitutes may result in injury to a physician's reputation, and will give dissatisfaction to the patient; hence, we trust that when physicians recommend or prescribe "Syrup of Figs" (Syr. Fici Cal.) they will not permit any substitution. The name "Syrup of Figs" was given to this laxative, not because in the process

# of Manufacturing

a few figs are used, but to distinguish it from all other laxatives, and the United States Courts have decided that we have the exclusive right to apply this name to a laxative medicine. The dose of

"SYRUP OF FIGS"

as a laxative is one or two teaspoonfuls given preferably before breakfast or at bed time. From one-half to one tablespoonful acts as a purgative, and may be repeated in six hours if necessary.

"Syrup of Figs" is never sold in bulk. It is put up in two sizes to retail at fifty cents and $1.00 per bottle, and the name "Syrup of Figs" as well as the name of the California Fig Syrup Company is printed on the wrappers and labels of every bottle.

OBJECT LESSONS IN GYNECOLOGY.

W. H. LINK, A. M., M. D, Petersburg, Ind.

V. PREPARATIONS FOR AN ABDOMINAL SECTION.

PREPARATION OF THE SURGEON.

There are a vast number of men in country practice who, for reasons best known and perfectly justifiable to themselves, have had no special training in abdominal work. Yet all of these men must at times face emergencies that demand a prompt resort to section. There is no time to send for a trained operator, for ere the message reaches him the patient is dead. Then, even if the case is one that can wait, the counsel sent for may be so busy that he cannot come. There is a class of patients who are too poor to pay even the attending physician, much less some specialist, who has calls enough on his generosity at his own door. So the emergency patients and the poor must put up with the aid near at hand ; and it is of prime importance that it be as good as circumstances and honest persevering effort can bring forth.

Any country doctor may at a moment's notice be called to a case of ectopic pregnancy with rupture, shock, internal hemorrhage and impending death. No time to send for the great Herr Professor Doctor Bock-bier. That belly must be opened and cleaned out, and that bleeding artery tied or a visit from the undertaker is the inevitable consequence.

Again, some child may be suddenly attacted with agonizing pain in the bowels attended with bloody mucoid discharges and a sausage-like doughy lump in the abdomen on one or the other side. A diagnosis of acute intussusception being promptly made, if the section is deferred till counsel is called from a distance, either adhesions will have become so dense, or tumefaction of the swallowed gut so great, or gangrene from constriction so far advanced, or shock so profound, or all of these so combined that when a section is resorted to, it will amount to no more than a autopsy on a living patient. Other forms of obstruction, such as volvulus, concealed hernia and dynamic obstruction from paresis due to appendicitis, are equally fatal if treated by procrastination.

In this day and age when fire-arms are so plentiful, penetrating wounds of the abdomen are not infrequent, while they, above all others, brook no delay, and death laughs at expectancy.

A deformed pelvis or a ruptured uterus may call upon the medical attendant at the most unexpected moment for a Porro, and the most hurried preparation will be none too rapid if a life is to be saved.

A fulminant case of peritonitis from a leaking or ruptured pus-tube, or ovarian scess, may cross the physician's path even in the night, and a rapid section with irrigation and drainage can alone save the patient from immediate dissolution.

These are not imaginary occurrences drawn from a "grandfather's tales," or

abstracted from a revolving library; for instances of every case named suppositiously have come under my own observation—except the ruptured uterus, and I have no reason to believe that my practice differs from the average practice of country doctors in general. If this be the general experience why should medical journals and medical writers waste so much time and space telling us that abdominal surgery is so intricate and difficult that only a chosen few ought to tempt fate by resorting to section? Why should they not spend more time and effort in teaching the benighted country doctor the correct principles of abdominal surgery? Why not dwell upon the severe techinque that makes work of this kind more successful in the hands of the tyro than when it is done by men of great experience without due attention to every detail and compliance with well settled principles?

Abdominal surgery need not be more fatal than any of the major surgical operations in the hands of the inexperienced if certain well established rules be followed. Certainly opening the abdomen and tying off a ruptured and bleeding fallopian tube does not require any more nerve or skill or knowledge of anatomy than to cut for stone or to ligate any large artery. Yet we are all expected to do these things in country practice. The great difference between abdominal and general surgery is that any defect in asepsis in abdominal and pelvic work is most likely to be attended by a large mortality; while in other surgery nature is better able to protect the patient from the mistakes of the operator. But this is no valid objection for any man can be clean while soap and water are so cheap and abundant. In general surgery, too, dirt may be, and often is, neutralized by the application of chemical antiseptics, which, if used inside the belly, would be more detrimental than other or accidental kinds of dirt.

In preparing for a section the first thing to consider is the surgeon himself. He should be *scrupulously clean.* The evening before doing a section he should take a bath and change his underwear for fresh ones. He should put on clean outside clothes, none of which have been worn while in attendance upon any septic case, or case of erysipelas. When preparing for the operation itself he should wear a long white apron fresh from the laundry. His sleeves should be rolled above the elbows and he should scrub his hands and arms with a good stiff nail brush, soap and water; the water being as warm as can be comfortably borne. This process should continue through several changes of water and for at least ten minutes. The nails being trimmed close should receive very careful attention with the brush. The brush itself should be sterilized in the same way as the sponges, in addition to being first thoroughly scalded. After the hands of the operator have been thus rendered aseptic they should not come in contact with any substance whatever, except boiled water. If, by accident or necessity, the operator should touch any object about the room, or any covering of the patient, he should at once scrub his hands again.

PREPARATION OF THE INSTRUMENTS.

The instruments should be put into a small shallow pan and, boiling water having been poured over them, they should be carefully cleaned with a brush and dried with a clean towel. The forceps should have all the joints of French locks bored out with the point of another forceps covered with a towel. Then rinse in hot water and carefully dry. Being packed away after this process they remain thus till taken out for an operation. Then they are put into a pan and have boiled water poured over them whence they are removed as needed. Instruments to be used in abdominal work should be packed in a *special* bag and *never used in any other surgery.*

LIGATURES AND SUTURE MATERIALS.

Scald the silk or boil it and stretch it before threading. Simply scald silk-worm-gut. For dressings, in my own work, I have always used the gauzes prepared by Seabury and Johnson, and I can say that I have never had a drop of pus in any wound made by my knife and dressed with such material. So I have confidence in them.

SPONGES.

Buy the very best and finest. Never use a sponge costing less than twenty-five to fifty cents. If properly treated sponges will last a long time and may be used for many operations. Beat and rub them well in order to get out all the sand possible. Then wash through several basins of cold

water and put in a solution of diluted muriatic acid over night. In the morning wash several times in cold water and drop into sulphurous acid (not sulphuric) 2:10 and leave twenty-four hours, then wash again and drop into absolute alcohol till needed. A self-sealing fruit jar makes a good receptacle for sponges and is always in reach of any one.

After using sponges wash them in cold water; rinse in warm water and drop into a basin of a solution of washing soda and let stand for six hours. Take out and wash and drop into a solution of sulphurous acid 2:8. After standing twenty-four hours wash and drop into alcohol. If the operation be on a pus or cancer case one had better burn the sponges.

BRUSHES.

The nail brushes should be carefully washed, then scalded and allowed to stand for twenty-four hours in sulphurous acid, when they are removed, washed in boiled water and dropped into alcohol till needed.

PREPARATION OF THE PATIENT.

The patient should be prepared for the operation at least forty-eight hours beforehand when possible. She is bathed and the hairy parts are thoroughly shampooed. Her nails are trimmed and carefully cleaned by scrubbing with soap and nail-brush. Just before the bath she is given a saline and this is repeated in teaspoonful doses every hour until her bowels are completely emptied. To assist the action of the saline, after the second dose she is given an enema of soap-suds. As soon as she is bathed she has clean clothes put on and goes to bed. For twenty-four hours before the operation all solid food must be withheld, and she must have no milk at all. Twenty-four hours before she is put on the table she is given a bath with alcohol and this may be repeated just before the operation. She must have a vaginal douche three or four times a day. Warm water with or without boracic acid, as one pleases. Immediately before operation her body clothing and the bed clothes are all changed for fresh ones.

After operation she is to have absolutely nothing, not even a drink of water for twenty-four hours. She may wash out her mouth with warm water but must spit it out. If she is persistently nauseated she may have a half a glass full of hot water to be drunk down at once. If nausea still continues, and especially if vomiting is bilious, she may be given $\frac{1}{10}$ or $\frac{1}{4}$ grain doses of calomel every hour for ten or twelve hours. If pain goes beyond tying pain give saline and shovel it in till catharsis is profuse. Clean the drainage tube every half hour at first, then less often till it is dry, then remove.

Drainage tubes for abdominal work should be of glass, open at both ends and perforated at the lower extremity for a distance of one or two inches with very fine holes. A very good and cheap syringe to suck out the tube with may be improvised by putting a gum catheter on the end of a large penis-syringe. Both should be new and made aseptic by washing and scalding each time before using. The strictest asepsis should be maintained while empting the drainage tube.

It is to be remembered that the prime factor in abdominal work is *cleanliness*. There must be absolutely no lapse in asepsis at any time, by either operator, assistants or nurse. To put the hands into one's pockets, or to rub the nose, or to brush back the hair, or to mop the sweat from the brow, is as grave a sin against asepsis as one need have his attention called to. The hand or finger that goes inside the abdominal cavity or that touches any of the abdominal viscera must come directly from sterilized water only.

Treatment of Delirium Tremens Wthout Chloral, Bromide of Potassium or Opiates.

Dr. Norman Kerr, in *The Quarterly Journal of Inebriety* for October, asks "if delirium tremens was a morbid state, which was the issue of neurasthenia, or an effect of alcoholic poisoning. He believes it to be the latter, and that the disease arose from the cumulative specific action of a poison on the cerebral tissue through the alcoholization of the blood." Acting on this belief, his treatment is to eliminate the poison from the brain and nervous system, and leaving the healing power of nature to do the rest. He avoids alcoholic liquors and opiates, chloral, bromide of potassium and all narcotics. He gives as the only medicine liq. am. acet., at first every hour in drachm doses, and as nourishment, milk, beef juice, broth. Coffee was frequently given.

THE SALIENT POINTS IN APPENDICITIS—ITS DIAGNOSIS AND TREATMENT.

JOSEPH HOFFMAN, M. D., Philadelphia.

For so hackneyed a subject it were almost necessary to apologize were there not so much variance in the views concerning it by those who, from experience or investigation, or both, have dealt with it in the light of its pathology as now understood—a pathology based upon a scientifically correct anatomy. Although demonstrated by Bardleben as early as 1849, and by Luschka in 1861, that the cæcum, and therefore the appendix, is entirely within the peritoneal cavity, the fact was ignored, and a perverse adherence to tradition substituted for demonstrated facts in all the teaching and discussion concerning the pathology of this region. Not until Mr. Treves, in his Hunterian Lectures of 1885, insisted upon an anatomy of this region now accepted as correct, was there serious attention paid to the value of surgical interference in a manner calculated to impress itself upon the general medical understanding, which is even yet handicapped by the weight of authority slimy with poultices and comatose with opium.

In order to appreciate certain pathological peculiarities in the position of the appendix after inflammatory complications, certain anatomical peculiarities of the cæcum are not to be overlooked. They will satisfactorily explain certain conditions otherwise puzzling. The cæcum itself is entirely surrounded by peritoneum which, after enclosing it, is reflected upon the posterior wall of the abdomen, being continuous with the ascending mesocolon when this fold exists. The cæcum, therefore, lies quite free in the abdominal cavity and enjoys a considerable amount of movement. The appendix is usually directed upward and inward behind the cæcum, coiled upon itself, being retained in its position by a fold of peritoneum which sometimes forms a mesentery for it.

The cæcum, therefore, hanging more or less free in the abdomen, is endowed with considerable latitude as to its motion. Rokitansky, describes these as threefold,—first, rotation upon its own axis; second, upon the mesentery as an axis; and third, upon another intestine as an axis. By rotation upon its long axis the cæcum may become so twisted that the ileum opens on the right side; but when revolving on its short axis the appendix may be placed toward the anterior abdominal wall, or it may be placed at the posterior aspect of the intestine. It will be evident that when these movements are combined there must be a resultant of motion, the location of the appendix varying accordingly as the movement of the cæcum. So far as the mesentery of the appendix is concerned, there is frequently a pouch between it and the ileum, consisting of folds of peritoneum which, from pressure by the rotation of the cæcum becomes, either congested or atrophied, and is thrown into a band or perforates—in either way becoming a source of danger to near-lying intestine, either as a strangulating cord, or as a ring through which a fold of intestine may fall and be choked in a hernial fashion. It is evident from these facts, that a purely physiological rotation of the cæcum may bring on a pathological congestion without the presence of any irritating matter whatever, and hence that in simple appendicitis where no concretion or fæcal deposit is found, we are to take into consideration such etiological factors, and not hastily conclude that the adhesions, limited simply by the peritoneal coats, have been previously caused by intra-appendical inflammation or deposit. Careful observation of such cases will reduce the number of instances in which an appendicitis is supposed to have healed by resolution.

A further point in connection with the variable position of the appendix is, that although this is variable, it is not abnormal but depends entirely upon the rotatory movements above referred to. A careful consideration of these facts in primary operations before there are universal adhesions with general pelvic implication, will be useful in determining, at least approximately, the position of the appendix, and so shorten the operation and prevent unnecessary handling of the intestines. Where operation is subsequent to repeated attacks, the anatomy is hopelessly con-

fused and careful, painstaking effort is required to get at the seat of the disease, and success is not always then assured.

Looking at the inflammations in the cæcal region from a purely anatomical standpoint, it is evident that their classification can and should be very much simplified. In a previous paper I ventured to assert that if we are to retain the terms perityphlitis, typhlitis and paratyphlitis, it should only be to remember that they are simply the sequelæ to appendicitis. This, of course, is not to be construed into a denial of the occurrence of stercoral colitis. This lesion is often within the range of probabilities, but has rarely been demonstrated. Dr. McMurtry's case, reported in the *Journal of the American Medical Association*, July 7, 1888, abundantly proves the real existence of perforative cæcitis, and also shows what refined skillful surgery can accomplish in this class of cases. But in dealing with disease it is facts we want, not names, and the nearer we can get down to a simple expression of causation, expressed in a certain well defined pathological exponent, by so much are we closer to a correct understanding of the pathological processes with which we have to deal. Hence, it is here well to consider in general terms that the appendix in real inflammatory conditions of this region, is the origin of the trouble, not denying that there may be possible exceptions to the statement, but arguing rather that the exception proves the rule.

Of late, there has been so much discussion of the necessity, advantages, time, etc. for operation in appendicitis that the procedure is itself no longer questioned in the so-called suitable cases. Methods, lines of incision, after-treatment, and the proper selection of cases, at present are receiving so much attention, that we must before long be placed in a light by which the operation can be more intelligently appreciated. Apropos of the former dilly-dally methods of treatment by opium, poultices, and funeral rites of the more serious cases, we have two classes of counsel in regard to operation. The first is that at once upon a real danger-signal—persistent pain, high temperature, and greater or less induration—operation should be resorted to. The surgeons of this order also advise resort to mild but efficient purgation to get rid of all extraneous pressure and to relieve congestion. Of the other faith are those who counsel waiting, with the argument that in reality very few cases of appendicitis result fatally, and that a great majority recover under rest and opium.

A third division now comes to the front, with the advice to operate between the attacks; in other words to wait for a recurrence before attempting operative relief. These latter surgeons really belong to the progressive surgeons of to-day. Foremost among them being Dr. Senn and Mr. Treves. Dr. Senn's argument for operation after a primary attack of appendicitis, before adhesions are universal or even moderate, in the presence of real suppuration or strongly suspected destructive inflammatory process, is logical from every point of view. It stands evident that if we are to operate, operation should be done before a complexity of adhesions exists rendering interference difficult or impossible. Mr. Treves in an article upon the treatment of relapsing typhlitis (*Brit. Med. Journal*, Nov. 1889) insists that in such cases the best results are obtained by operating after all inflammatory and other symptoms have ceased. A careful examination of the argument of Mr. Treves shows that he considers the subject from an altogether different standpoint from Senn. Dr. Senn would have us operate before there are serious inflammatory complications, and dwells particularly upon the safety of such operation. Treves, on the other hand, argues for relapsing cases, and from his conclusions evidently has in mind the worst possible cases. Viewed in this light his argument falls short and is assailable. If we are to operate, for how many recurrences are we to wait? Then again if there is a perforating appendicitis, how do we know that the inflammatory symptoms will subside at all? What we do know is that the longer the inflammatory symptoms persist the greater will be the complications, and the less will be the strength of the patient to endure operation if it is finally resorted to. The argument of the recurrence of the disease against operation by opponents of early operation is, I think, used fallaciously. Fitz's tables records a recurrence of eleven per cent. Those of Kraft, are double this or twenty-two per cent.

From the anatomy of the parts above referred to, it is evident that many cases

of appendicitis are limited to simple inflammatory peritoneal adhesions, and are really not appendictis at all, and hence have little or no tendency to recur. In general statistics, these are all included under a general head, when if excluded, they will both reduce the number of cases of appendicitis, and increase the number of recurrences in actual disease. To these may also be added cases of stercoral cæcitis, which are also reckoned as coming under the head here discussed, but which are really entirely distinct from it. If we take out these from the whole number of cases, the average of recurrence is still further increased. Cases coming under these two latter heads, are those which most frequently yield to the routine treatment, and which are therefore put down as cured without recurrence.

In distinguishing these forms from the serious or perforating and ulcerative varieties of the disease, the treatment has much to do. A simple inflammatory congestion may result in peritoneal adhesions and get well without treatment at all. This we find constantly in the abdomen. A stercoral impaction under opium and calomel will finally be relieved, though why it will not be relieved by calomel alone if relieved by both, is one of the mysteries of therapeutics. But if there is a real perforating ulcer what is there curative in rest, opium or poultice? Or what advantage is there in it, since there is at least danger of recurrence in twenty-five per cent. of cases, with the danger of peritonitis increased in each recurrence, and the need of operation almost imperative if we would give the patient any chance? Recurrent cases must be regarded as the typical cases of this disease, and those which do not recur, and give no further symptoms after prompt depletive measures to relieve congestion, as having little more relation to them than has roseola to scarlatina. That concretions may exist in the appendix without giving rise to inflammatory trouble does not invalidate the general rule that ordinarily they cause suppuration.

But when we have concluded to resort to operation what plan are we to pursue? Here we are to be led by the principles of abdominal—not of general, surgery. We are not for instance to be led by Mr. Treves, who falls into the egregious error of considering abdominal surgery nothing more than general surgery. Treves would have us separate all adhesions by the knife, just as on the post-mortem table the pathologist secures his specimens. Such advice must only come of insufficient observation of the work of true abdominal surgeons, and from an experience which is too small to be generalized. Dr. Homans, of Boston, cautions us against the use of the drainage tube, saying, "Drainage tubes in the abdomen are apt to be followed by fistulæ." Dr. Homans has not the right to condemn the drainage tube except from his own experience. In the hands of many the drainage tube has yielded the greatest satisfaction, as you have already heard. Mr. Tait says it decreases his mortality from ten to fifteen per cent. Careful cleansing of the tube will prevent the objections to its use and free it from an odium unmerited. Mr. Treves falls into the same error, when he says the drainage tube should not be used. In abdominal work, no surgeon, whatever his ability, can lay down a rule which can remotely hope for constant observance so far as drainage is concerned. So far as Mr. Treves' anatomy is concerned, it is very good, the best; so far as his surgery is concerned, it is fair to say in many respects it is very bad from an abdominal standpoint. This is especially evident if we attempt to follow his directions in cases in which we are not able to remove the appendix, either from the nature and extent of the adhesions or the condition of the patient. In the presence of such a suppurating, sloughing mass, the only thing to do is to open up and get down into the suppurating cavity, remove all debris possible and introduce a drainage tube to allow the escape of its poisonous contents.

The differential diagnosis of inflammation of the appendix from other diseases of the abdomen and pelvis, is not always easy. It is more difficult in women than in men. Many of the affections however that have been confounded with it in diagnosis ought to be excluded by careful examination. Such are renal and biliary colic, ovarian neuralgia, traumatic rupture of the intestine and the like. It is important to remember, that in urgent symptoms, positive diagnosis is not called for, and that exploratory incision is not only justifiable but demanded.

In men the presence of an indurated

mass in the right iliac fossa, together with the detection of fullness and pain by rectal examination, is an important point in diagnosis. The right leg is often drawn up, and there is tension of the abdominal parietes over the cæcal region. A chill often is a concomitant of perforation and peritonitis. Mr. Tait records a case in which he diagnosed suppuration at the base of the kidney, but which was shown by exploratory incision to be a "perityphlitic" abscess. He says: "The history has been most carefully gone into, and even now in going over the case, I do not see how we could have come to any other conclusion." The differential diagnosis from hernia is generally easy, though cases have occurred in which the appendix has been found in the inguinal canal and scrotum. McBurney (*N. Y. Med. Jour.*, Dec. 1889) lays especial stress on his observations going to prove that the point of the greatest tenderness, discoverable by a single finger-tip is, in the average adult, almost two inches from the anterior iliac spine, on a line from this process to the umbilicus. It is not probable that in all cases the exact spot of greatest tenderness will be even approximately the same, but even if in a smaller number of cases it is found to correspond, it is to be considered a valuable point in diagnosis.

The value of puncture in diagnosis of appendicitis, to determine the necessity of operation from presence of pus, has been variously discussed for and against. Here difference in opinion stands out prominently. But the fact remains that if used it can do no good, and when used it is only, or should be, when other symptoms point prominently to the pus. If puncture is negative, so far as positive evidence of pus is concerned, it is misleading and may do infinite harm. I believe it should never be used therefore and should be condemned.

CLINICAL LECTURES.

PROLAPSE OF THE WOMB FROM HYPERTROPHIC ELONGATION OF THE SUPER-VAGINAL PORTION OF THE CERVIX—SUPERNUMERARY OVARY WITH VENTRAL HERNIA—PYO-SALPINGITIS—NERVOUS OVARIES.*

WILLIAM GOODELL, M. D.

Gentlemen: This patient, forty years of age, was married when she was twenty-three years of age and has eight children—the youngest is eight years old. She says her womb comes outside of her body, which fact she first noticed eight years ago.

In order to pass her water she is obliged to get on her hands and knees and force the uterine mass back into the vagina. Her trouble is due to a prolapse of the womb, through hypertrophic elongation of the supra-vaginal portion of the cervix. The bladder is almost wholly outside of her body and that is why she has to pass her water in the manner described. I have not seen this case before. The doctor who examined her said that the uterine measurement was five inches, but I do not find it to be over four and a half inches. This shows that the uterine tissue is somewhat elastic, varying in length under varying conditions of traction. When the mass is outside of the vagina it gives a longer measurement than when it is pushed back into the vagina.

Here we have a tumor protruding, the ordinary term is prolapse of the womb, but it should be designated a prolapse of the cervix. The front of this mass is the anterior wall of the vagina and the bladder is behind it. The posterior wall is also, to a certain extent, involved. You see that there is a tear of the neck of the womb, and this very tear has been probably the initial point or cause of her trouble. Why? The unhealed cervical tear caused an irritation which invited blood to

*Delivered at the Hospital of the University of Pennsylvania; reported by Lewis H. Adler, Jr., M. D., Late Resident Physician at the Episcopal Hospital and the University Hospital.

the parts. This overnutrition caused growth and congestion, and these produced weight and traction. Hence the cervix was pulled down and with it the bladder which is fastened at that part. This elongation is covered with a delicate epithelium, which is very sore, almost raw.

Here comes the difficult point. We do not know whether the bladder began to prolapse as the first step in producing the condition existing in this case. It is a mooted question as to what causes this condition, whether it is produced by actual hypertrophy or by traction. Here is a woman who has had a tear of the neck of the womb causing cervical hypertrophy. When the bladder comes down she is obliged to bear down quite forcibly in order to pass her urine. This straining, aided by the weight of a full bladder, elongates the supra-vaginal portion of the cervix. We therefore believe this trouble here is due to traction.

Here then we have a vagina turned inside out. The danger in an operation in this case is of cutting into the bladder and into Douglas' pouch. We have no means by which we can measure the extent downward of the latter. In any event, we ought not to get into the bladder. Many a gynecologist however has done so. I generally pass a sound in the bladder and if I do not feel satisfied with the examination then I pass in my little finger. I have myself cut into Douglas' punch but never into the bladder.

The affection under consideration, usually occurs in women who have borne children, but sometimes you will find it occuring in old virgins, women sixty and seventy years of age. In such cases however it is not so large. Now the operation here would be to amputate the cervix, after which the wound would be closed up, by what we call "Hager's Spokes of the Wheel Suture." Forcible pressure is made by means of this suture and hemorrhage is thereby prevented. It will require in this case an amputation of one-half an inch of the cervix as there will then be absorption, by retrograde change, of the redundant portion of the womb. We have also to perform an operation to restore the torn perineum, which, in its present condition, affords no support to the internal organs whatever.

Afterwards she should be able to wear a pessary. There are very few women with this kind of malady who can wear this instrument. With these two operations and the subsequent use of Smith's pessary, we can, in a measure accomplish a cure. In these cases a gynecologist cannot promise to cure as he can in other operations. There may be a return of the disease in time. There is, however, very little danger in an operation of this nature.

This woman has just told me that I performed an operation on her torn cervix three years ago. I had forgotten the fact. She says I put thirteen stitches in. This operation did not do her any good. She was to have come back but never did.

Sometimes a woman will get pregnant and this trouble will return; sometimes even without the aid of pregnancy. One of the operations advised at the present time is to close up the vagina. That prevents coition. When a woman has not borne children and has this trouble, as she occasionally will, then in that woman the projecting portion of the womb looks like the male organ in a state of erection. These are cases which require amputation of the cervix. I think I have seen only a half a dozen of such cases. There is no earthly use in putting any kind of a pessary into this vagina, unless it is a stem and cup pessary. It is sure to come out.

SUPERNUMERARY OVARY WITH A VENTRAL HERNIA.

The next case is an interesting one of a most surprising diagnosis. The patient is twenty-eight years of age and has been married eight years. She has two children, the youngest four years old. She complains of constant pain in the region of both ovaries, worse on the left side. It passes along the left thigh into the knee-joint, showing that there is an ovarian nerve involved. She has back-ache and frequent vertigo. Her menstrual periods continue at regular intervals and last four days. According to her statements a year and a-half ago a physician operated upon her and removed her ovaries. Four months after the first operation she had, on account of pain and a continuance of menstruation, another laparotomy performed and the gynecologist said that the ovarian tissue had been removed. In spite of this her menstrual periods still continued.

She had two laparotomies performed. She asserts this positively, yet possibly it may have to be taken with some allowance. Notwithstanding these operations she is worse than before. I do not know that I shall be able to find the cause of her trouble. We have here a very excellent perineum; there has been a very trifling tear of it. You may also notice the remains of the hymen. She has had two children with no internal tear. It is a perplexing case to decide. I did look upon it as a case of adhesions of some intestinal loop and I still think such to be the case. We will first see whether the womb is movable. I pass in the uterine sound. There is a little resistance here which may be from the shortening of the ligaments by the operations. Now I give the sound a sharper curve, so that it will be impossible to turn it inside of the womb without twisting the womb itself on its axis. I find that this organ is in a fairly good position—looking a little bit to the right—there is no disease here. There is no resistance where I press it over to the right, so that there is no fixation of the organ for it is sufficiently movable. Now the next question is, why does she menstruate? That is the puzzle. I do not find anything out from this examination explaining the continuance of the monthlies.

I shall now make an examination per rectum to see if I can discover anything there. Yes, there is a body here on the right side which ought not to be there. It is about the size of an ovary and seems to be attached to the womb, as an ovary naturally should be. I can give some movement to it and it seems slightly cystic. But nothing but an exploratory incision will tell me what it is. This woman has a hernia, as a result of one of her former operations, but it can be cured by the operation I shall perform, if she only gives her consent.

I have told you of the possibility of supplementary ovaries, and also that in my cases, after a certain length of time, the patients all stopped menstruating.

I shall ask this patient if she will submit to an operation and act accordingly. Sometimes adhesions to the bowels produce a good deal of pain. Here we have a movable womb, no adhesions. What the body is that I felt per the rectum I am not prepared to say; it feels very much like an ovary.

The operation here would be to perform a laparotomy, removing the cicatricial tissues, which will be found existing in the reunited edges of the old incision of the operation, and then to bring the freshened edges of the abdominal walls together by means of silk and catgut sutures.

PYO-SALPINGITIS.

Here is a patient twenty-eight years of age who has been married eleven years. She has had two children, one is seven years old and the other eight. She had a miscarriage when three months gone about five years ago, and has not been well since. She has had metrorrhagia for five years, that is constant bleeding from the womb. She complains of pain in the left ovarian region. It is exaggerated by walking or by lifting. The symptoms look like those of some tubal trouble. She has leucorrhœa. One week out of four she spends in bed. She is very nervous naturally. She is obliged to go to bed because she has pain.

Before this miscarriage which she had she received a kick in the abdomen and the pains began in three or four days afterwards. This injury caused a separation of the placenta, and the ovum became a foreign body. Fortunately her womb was not large enough to hold much blood or she might have died from internal hemorrhage. She says that she had an attack of peritonitis after this kick, and has occasional attacks even at the present time. Yet the case may be one merely of nervous ovaries. Sometimes indeed it is difficult to decide whether we have a case of diseased, or of nervous ovaries to deal with.

I find in this case that the womb is turned over backwards—a suspicious circumstance. On the left side I find an enlarged ovary. The womb is badly retroverted. When this is the case after an attack of peritonitis, in the majority of cases, you will find evidences of some tubal or ovarian trouble. I pass in this uterine sound, and ascertain that the womb has impaired mobility. I should say that there is extensive disease there, but before this can be decided positively she will have to be etherized. There is probably a pus tube on the left side. I

mean by that, a fallopian abscess. She had a miscarriage which resulted from traumatism—from the kick. The blood escaping from underneath the placenta became putrid and septicæmia followed. The ovary is usually secondarily affected by inflammation. If she has pus there it explains her history of a good deal of groin pain, of trouble with the monthlies, difficult locomotion, etc.

The danger of death in these cases from bursting of the tube into the peritonial cavity is greatly exaggerated.

This might happen but it is a very rare complication. My advice to this patient is to submit to an operation, for she will never have another child, the ovaries being so diseased that she is practically without them.

NERVOUS OVARIES.

The last patient I shall show you today is aged 32 years. She has had five children, and has a slight tear of the cervix, but not bad enough to need an operation. She complains of backache and of constant pain in the ovarian region. Her menstrual periods are regular, but they upset her nervous system. The diagnosis in these cases is sometimes very perplexing. I get hold of some that puzzle me greatly.

Is this person suffering from the effects of a diseased ovary, or has she the affection rightly designated as "nervous ovaries?"

She has symptoms of diseased ovaries and yet they may not be organically diseased.

When we find a fixed ovary it is plain sailing; but when it is movable, it is often puzzling to decide, and many a woman has lost perfectly healthy ovaries by such counterfeits of organic disease.

I find that the patient wears a pessary, which keeps the womb in perfect position, so you can exclude that organ as a cause of the pain. She has all the symptoms of nervous ovaries. She dreams at night, has sleeplessness, nervousness arising from family troubles, etc. She has palpitation of the heart; has numbness in her hands, and sometimes thinks she is going to have paralysis.

The best treatment then is a preparation of bromide of some kind. Ten grains of ammonia bromide and five grains of ammonia chloride makes a good prescription. My Sambul pill is another good remedy. Then absolute rest in bed should be enjoined for an hour a day at least. No one should be allowed to even approach her room, if that is possible. Massage is most important and if this patient were able to pay for such treatment I should order her to have a person to rub her daily.

COMMUNICATIONS.

ABSCESS OF FRONTAL SINUS—REPORT OF CASE—OPERATION.*

G. A. WALL, M. D., Topeka, Kansas.†

Cases of abscess of the frontal sinuses are certainly not met with very often, while simple catarrhal inflammations of these sinuses are of frequent occurrence. It is for this reason that I report this case, and again the diagnosis and treatment being, as a rule, easy, it is well that you should know how to take care of a case should you meet one, which you are liable to do at any time during this season of the year when colds are prevalent. The operative procedure is not one so great, but that any one with the slightest knowledge of anatomy can do, and there is little if any risk to be taken.

The literature on this disease is not extensive, as most of the authors devote only a few paragraphs to it, some none at all. Bosworth[1] and Fowler[2] have written the most extensively on it. Bosworth's[3]

* Read before Eastern Kan. Med. Society at Topeka, Kansas, Jan. 12, 1893.

article is complete and well worth your perusal.

As to the occurrence and causation of this disease, permit me to quote from some prominent authors. Bosworth says: While simple catarrhal inflammation ofthe mucous membrane of the frontal sinuses occurs in connection with a cold in the head more frequently than that of any of the other accessory sinuses, suppurative inflammation on the other hand is one of the rarest occurrences. This is probably due to the fact that the infundibulum opens from the most dependent portion of the cavity thus affording free drainage while at the same time it is less liable to become occluded." Zukerkandl states that he never met with a ‡ *single instance of uncomplicated disease* of the frontal sinus. Agnew[4] says he only saw one instance where the inflammation occurred in the sinuses independent of any pre-existing affection of the nasal passage. Noys[5] is also of the opinion that this disease is consecutive to some nasal trouble, for he says: "It is necessary in all these cases to examine the nasal cavities and sometimes the cause will be found in hyperthophy of the middle turbinated bone."

The disease may arise as the result of any condition causing occlusion of the orifice of the sinus or from any obstruction in the nasal passage, but Bosworth says that from these causes it is exceedingly rare. He thinks that the most active agents in its causation are traumatism, maggots in the nose, gonorrhœa, syphilis, scrofula, or the development of tumors within the sinus itself. The disease does not occur until after puberty, as the sinuses are of small size or entirely absent during childhood, after which time they undergo considerable enlargement from recession of the brain. Large frontal sinuses do not necessarily imply large external prominences over the glabella and supercilliary eminences. They are lined with mucous membrane which is the continuation of that from the middle meatus of the nose extending through the infundibulum.

The symptoms as given for this affection are: Frontal headache, generally intense and increasing as the accumulated secretions gather and distend the sinus; it is usually persistent although it may assume an intermittent type, being attended with nausea and vomiting; mental effort increases it. There will be swelling, an erysipelatous blush and oedema over the sinuses. There will also be rigors and fevers, anorexia and sleeplessness. In my case all these symptoms existed; but in a case reported by Dr. Lanphear, the only symptoms present were intense frontal headache and fever in the earlier stages.

If the pus accumulation is large and the exit obstructed the roof of the orbit may be crowded downward so as to produce displacement of the eyeball and diplopia, and amaurosis ensue. If the posterior wall of the sinus is displaced it will be indicated by symptoms referable to the brain, such as dullness or apathy and sleepiness. The brain symptoms are usually obscure for the anterior lobes, although Otto cites a case where displacement of the posterior wall of the sinus gave rise to unilateral paralysis. If the pus escapes into the brain cavity menigitis supervenes. And again, cerebral abscess may develope without perforation of the bony walls of the sinus.

The diagnosis will be easy as a rule, the symptoms I have given being present in part or together.

The following case came under my observation a short time ago:

On Dec. 28th, 1892, was called to Silver Lake, Kansas, in consultation with Dr. Dudley to see Mr. L. C., æt. 45, a telegrapher, who gave the following history: About three weeks ago he "caught cold," and the nose seemed to stop up; since then he has been having frontal headache, which has been increasing in intensity; temperature ranging about 101° F., with chilly sensations; swelling and oedema very great, extending across the forehead, especially on side corresponding to the affected sinus, down towards the base of the nose and into the orbit, at the inner canthus. There was an erysipelatous blush, and the parts around were very painful to the touch. At first sight it appeared as if the pus had penetrated the orbital plate, but on careful examination, no fluctuation could be felt and subsequent events proved that it had not. We concluded that we had a case of frontal

‡ Italics are mine.
(4.) System of Surgery, Vol. III., Page 117.
(5.) Noyes' Diseases of the Eye, 1890.

sinus abscess, and that the only thing to do was to open the sinus, which we did in the following manner: The patient being thoroughly anæsthetized, I made an incision one inch long just above the left eye-brow extending almost to the median line; the œdema being so great it was almost one inch in depth. I was compelled to make a vertical incision one inch long, beginning at the nasal end of horizontal cut. I then made use of the angle formed by the junction of the two incisions as a land-mark for the site of my perforation as it was very difficult to locate the proper position on account of the great œdema. The point of perforation being about ¼-inch above and internal to the inner angle of the orbit. I trephined at this point and a great amount of thick creamy pus escaped—I should say almost an ounce. The wound was then well washed out with a weak solution of bichloride of mercury and dressed with bichloride gauze. Owing to the fact that we had no drainage tube at hand no drainage was used. The operation was done at 3 P. M., and the patient rested well all the succeeding night. The following day I saw the patient again and found him doing well; temperature normal; pulse 72; no more pain or headache, and little if any discharge; swelling and œdema decreasing and patient feeling very contented. The last report was on Jan. 10th, at which time Dr. Dudley writes as follows: "I should regard C.'s condition as in every way favorable. There is some little discharge daily, probably the most of which is serum from the external wound. I wash it out with 1–5000 bichloride solution and follow with peroxide of hydrogen full strength. This has been the treatment all through the case. He has had no symptoms that did not indicate a favorable ending.

"Since the above was written a probe has been passed through the infundibulum into the nose, thereby establishing a free opening into the nose from the sinus."

AN ATTEMPT TO MAKE A RADICAL CURE IN THREE CASES OF HERNIA.

J. S. WRIGHT, M. D., Brooklyn, N. Y.*

The first case was one of congenital hernia of very large size. The second case was a large strangulated hernia in a healthy sailor thirty-seven years of age. The third case was a tightly strangulated hernia in a feeble woman fifty years of age.

Case I. November 12th, 1891, I went with Dr. Gunther to see W. W., a two-year-old boy, who had a very large congenital hernia of the right side. When the hernia was fully down it was as large as a child's head. It was easy enough to reduce it, but it was impossible to keep it up. I advised an operation for radical cure, even if it did not succeed, for the patient's condition could not be more unfortunate than it was. At my request the patient was taken to the College Hospital, where I operated December 20th, 1891. I operated as if the case were one of strangulated hernia. The sac was organically continuous with the musculofibrous structure of the scrotum, and after opening it, the large quantity of coiled up intestine could not easily be put back into the abdominal cavity; the intestine had to be held in, in order to prevent it from escaping. Then I dissected up the entire sac, testicle, spermatic cord, and the involved tissues as far as the internal ring. Close to the internal ring I put a strong cat-gut ligature around the neck of the sac and tied it firmly; then I cut off the entire sac, as well as the spermatic cord. The cord was atrophied, and was continuous with the connective tissue of the sac. It would have been quite impossible to close up the sac at its neck, without removal of the cord and the testicle. I closed up the entire wound with deep sutures with the intention of obtaining primary union. The soft parts were severely injured by the operation, and much inflammation followed, making it necessary to remove the sutures at an early day; yet the wound over the seat of

*Professor of Operative and Clinical Surgery at the Long Island College Hospital, Brooklyn, N. Y.

the canal repaired by primary union. Four or five days after the operation the patient had a severe attack of scarlet fever along with other children in the same ward. The attack terminated favorably and did not seem to have any deleterious effect upon the reparative process. In the mean time the boy would get out of bed and amuse himself playing with the other children in the ward. The patient was discharged from the hospital February 2nd, 1892, apparently with a radical cure.

Case II. W. M., a sailor thirty-seven years of age, was admitted to the College Hospital, January 25th, 1892, having a very large strangulated hernia of the right side. A persistent effort to make reduction had severely contused the hernial sac and its contents. The patient was suffering severe pain and the shock was serious. The result of an operation was considered doubtful. I opened the sac in the usual way and found a large quantity of omentum which had been contused so that it contained considerable blood in its folds; and the omentum had been twisted into several dependent portions. There was a small part of the ileum in the sac, but it was readily reduced. The spermatic cord was dislocated from its usual or normal location, and was entangled in the omentum from the testicle upward to the abdominal cavity. The protruding omentum was quite irreducible, so I ligated it in three parts, one of which included the spermatic cord; another ligature was put on the spermatic cord just above the testicle; then the entire omental mass was cut away, and the stump put just inside the internal ring. The sac was dissected up as close as possible to the peritoneum, and the neck of it was tied with a strong cat-gut ligature and then cut off. The entire wound was closed with deep silk sutures. The part in the inguinal canal healed by primary union, and the part in the scrotum healed by granulation. This patient was allowed to get up in about five weeks. He went about the ward for two or three weeks more, and then began to help as orderly; he remained in this position for several months, and in the mean time seemed to have a complete radical cure.

Case III. A married woman, fifty years of age, February 24th, 1892, was sent to the College Hospital by her family physician. She was suffering from a strangulated hernia of the left side. The hernia had been down for about three days, and had been strangulated about twenty-four hours. When I saw her the hernia was irreducible, she was suffering much pain and the shock was severe. Her pulse was feeble and intermittent, and she had become indifferent as to the result, readily consenting to an operation. When I got down to the neck of the sac, I found the constriction very narrow, and could get under the upper band with much difficulty even with a small tenotome. When the knuckle of intestine was first exposed it looked as if it were gangrenous, but in a few moments the circulation began to be restored. And so confident were we that the strangulated intestine would recover that we put it back into the abdominal cavity. Then I dissected up the sac as far as the internal ring, and tied the neck of it with a strong cat-gut ligature, and then removed the entire sac. The wound of operation was closed completely with aseptic silk sutures; I caught the sheath of the femoral canal by the suture in order to prevent the hernia from escaping in the future. Primary union occurred throughout the wound; the opening through which the hernia came was obliterated, a firm wall of resisting material being formed. The patient made a good recovery and has had no return of the hernia.

The last case shows the importance of removing the sac or, at any rate, of obliterating the neck of the sac so as to restore the continuity of the peritoneum at the internal ring. In the second case the testicle had become so much atrophied as to be useless, and the spermatic cord had become so entangled in the omentum as to make it desirable and advisable to remove it, and thus facilitate the obtaining of a radical cure. This case only shows that the spermatic cord may be removed in exceptional cases. In the first case there was no visible spermatic cord, and the testicle was of the most rudimentary nature; an attempt to save it would have failed.

Hemorrhage from the Stomach or Bowels.—Tannic acid, ten to fifteen grains, if due to capillary oozing. If from typhoid fever or ulcer of the stomach, treat as for pulmonary hemorrhage.

TWO CASES OF SUPPURATIVE INTRA-PELVIC INFLAMMATION WITH SPECIMENS.

L. S. McMURTRY, M. D., Louisville, Ky.

Both cases are of long standing salpingitis associated with recurring attacks of pelvic peritonitis, going on to accumulations of pus and involving the ovaries and adjacent folds of peritoneum in the destructive inflammatory process.

In the first case you will observe that the fallopian tube is as large as the small intestine and filled with pus. The ovaries are cystic, a degenerative process often associated with long standing inflammation in the uterine appendages. This photograph shows the firm and universal adhesions which fortunately I succeeded in detaching without rupture, either of the tubes or the cystic ovaries. The patient is a young married lady, aged thirty-two, and had a history of long standing pelvic inflammation; a history formerly familiar to the profession under the mistaken and erroneous pathological term of "pelvic cellulitis." When suppuration occurred all the usual symptoms supervened, such as fever and sweats. The enucleation of these masses from the deep pelvis is rendered difficult by the dense adhesions which become organized, rendering injury to bowel and bladder a frequent complication. If removed early in the course of the disease the operation is less difficult and less dangerous. This patient made a good recovery.

The second case is also one of suppurative salpingitis and peritonitis of long standing; such a case as is usually designated as pelvis abscess. It is the only fatal one of a group of abdominal sections which I did last week.

The patient was thirty-four years of age; married; never robust and never conceived. She had undergone various methods of local treatment for uterine disease and about a year since submitted to forcible dilatation of the cervix for dysmenorrhea and sterility. Since this time she had active intra-pelvic inflammation. Seven months ago she became confined to her room and bed with symptoms of suppuration. She had high fever with rapid pulse and sweating, followed last autumn by rupture into the bowel and general septic symptoms. The opening into the bowel was small and the abscess sac was never entirely emptied. It would discharge for a time, then the opening would close and she would again have fever. I saw her in the autumn and advised immediate operation; the operation was done last Thursday. The patient had a feeble and rapid pulse and was reduced by prolonged septic fever.

As can be readily seen from the specimen the operation proved to be of exceptional difficulty. On the right side the fallopian tube and ovary were converted into a large pus sac, which was as large as the fully distended bladder. It was firmly attached by organized adhesions to rectum and bladder; it seemed continuous with both rectum and bladder. Its enucleation taxed my digital endurance to the utmost and necessitated great care to avoid injury to bladder, bowel and ureters. The appendages of the opposite side, as can be seen, were extensively diseased—a large pyo-salpinx and par-ovarian cyst. The operation was thorough, and completed in about thirty minutes. The patient was put to bed without any appreciable shock. Six hours after the operation the catheter showed complete suppression of urine, and this continued for fourteen hours, when the kidneys resumed their function. The pulse, however, remained high and death occurred from exhaustion on the fourth day.

The condition disclosed by operation in these cases is a plea for early interference in this class of cases. It is altogether an error to suppose that cure can be affected in such cases as this either by spontaneous opening into the bowel or by puncture through the vaginal vault. To examine this specimen will satisfy anyone upon this point. After discharging the sac re-fills, and septic infection and suppuration will go on for years if the patient can hold out, and then the cure will not be completed. The proper treatment of these cases, and the only treatment which can avail, is early and thorough removal of the suppurating mass before the patient is exhausted by prolonged suppuration. When the sac ruptured in the course of the operation in the second case reported the pus ran freely out on the table and was very offensive. The case illustrates the most advanced and extreme ravages of inflammation and suppuration within the pelvis.

SOCIETY REPORTS.

THE CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting of December 27th, 1892.

The President, Dr. I. N. Bloom, in the chair.

AMPUTATION AT THE HIP; RESECTION OF THE RIB.

Dr. A. M. Vance: I simply present this patient, boy aged eleven years, to the Society to show the result of amputation at the hip for suppurative hip-joint disease, and resection of the eighth rib for effusion in pneumonia.

The history of the case is about as follows: I first saw the patient in September a year ago and diagnosticated suppurative disease of the right hip-joint. As is often the case in children of this age, the course was rather rapid, an abscess forming in Scarpas' space with evidences of excessive bone disease. Aspiration was practiced several times without any great success. In March, 1892, the boy was put in the Childrens' Hospital and the abscess opened and irrigated. The opening was followed by a long season of sepsis without any reparative action whatever going on. At the time the abscess was opened I discovered that the partition of tissue between the femoral artery and the abscess cavity was exceedingly thin, therefore no drainage tube was inserted for fear sloughing would take place and at the time I prognosticated possible rupture of the femoral artery.

After a month of high fever, excessive discharge of pus from the abscess, hectic condition, etc., I was called by telephone to the Hospital at three o'clock one morning, the message being that the patient was bleeding profusely. Upon examination I found that the femoral artery had spontaneously ruptured into the abscess sac, the patient being thoroughly exsanguinated. The artery was ligated by candle light, and the leg wrapped in cotton wool and elevated. At the end of forty-eight hours the foot was gangrenous and, notwithstanding the fact that the patient was barely alive—temperature 104.5° F., pulse beyond counting—amputation at the hip was decided upon.

When the patient was put upon the table for operation his pulse was hardly perceptible at the wrist, probably about 170 to the minute. The femur to the extent of about four inches was found to be very much diseased and the acetabulum also being involved. I did not make any attempt to clean it, believing that nature would do so, my object being to get the patient off the table as soon as possible owing to his extreme condition. The time consumed in operation, from the moment anæsthesia was half complete until the dressings were applied and the patient put in bed, was about nine minutes. Whiskey and nitro-glycerine were given hypodermatically after the operation; reaction came on slowly; convalescence gradual. There was very little hemorrhage during amputation, the femoral having previously been litigated on account of rupture.

About two months after this he was taken suddenly sick, and it was found upon examination that he had an attack of double pneumonia, both lungs being extensively involved. He was still in a very hectic condition, having recuperated but little from the state of depression at which he had arrived, owing to the amputation. His case was given up as hopeless, all efforts toward helping him except to make him as comfortable as possible, being discontinued.

However, the crisis came on the third day after the attack, and he slowly began to convalesce. His right lung cleared up very nicely but the left one remained dull, apparently solid. Upon careful examination we found that there was an immense accumulation of fluid in the left side of the chest which was tapped three times; at the first aspiration we removed three and one-half pints of fluid; the second time two pints, and the third time two pints, a pint of which was pus. The heart at this time was beating way over to the right side, showing the extent of the effusion. The condition of the patient was now equally as alarming as before the amputation, and as the aspiration was doing no apparent good, I advised that

another chance be given him and the excision of a portion of the eighth rib be done.

This operation was performed about a week after the last aspiration, the chest being thoroughly washed out with hot water and two large drainage tubes inserted. Time consumed in this operation was seven minutes. Irrigating the cavity of the chest was done in a very thorough manner, throwing the water in through one tube it came out through the other, each inspiration working like a force pump. The drainage tubes were allowed to remain in about ten days, then removed and a pledget of gauze inserted, which was also removed in a few days, the wound healing perfectly. The patient has entirely recovered the use of his lung as will be observed by deep inspiration, and there is bony renewal of the excised portion of rib. I think this will be obtained in nearly all cases if the precaution is taken, as I did in this case, to slit the periosteum, turning it back and simply removing the rib itself, leaving the periosteum intact.

I consider this a very remarkable case, the patient having gone through two grave operations and double pneumonia, inside a period of three months. There is one thing certain, that without Hospital advantages, the boy would probably have died in either operation. There is now no evidence of tuberculous trouble, and I think his ultimate recovery is assured.

DISCUSSION.

Dr. W. C. Dugan: I had the pleasure of assisting Dr. Vance in the operations referred to upon this patient and I consider it one of the most remarkable cases on record. I also think that a case of this kind is extremely rare. Many would not have attempted an operation in such extreme conditions. Rapid surgery saved this boy's life.

Dr. L. S. McMurtry reported two cases of "Suppuration Intra-pelvic Inflammation, with Specimens." (Page 170)

DISCUSSION.

Dr. J. M. Krim: If I understood correctly, for fourteen hours after the operation there was complete suppression of the urine. I would like to inquire as to the quantity secreted after that time.

Dr. L. S. McMurtry: There were no general symptoms of suppression of urine. That the bladder was not injured was demonstrated by the fact that the patient afterward, without the aid of a catheter, passed urine which, of course, could not have been done had the bladder been injured. The suspension of the action of the kidneys for some hours after the operation is significant as showing the impaired nutrition from prolonged septic toxæmia.

Dr. W. H. Wathen: I do not know that there is anything I can add to what has been said about the first operation. The specimens of the second case are interesting, illustrating two diseases that are occasionally found co-existing in the pelvic cavity; one of inflammatory or septic origin, the other (the tumor) the result of some unknown cause. Had the case been operated upon before the abscess ruptured into the rectum the diseased structures could have been more easily enucleated and removed. But after rupture into the bowel, complications arise which make the operation difficult and dangerous, and we never know the conditions to be treated until the abdomen has been opened. Even then it is sometimes impossible to know the condition of all the structures in the pelvis until the operation has been completed.

The reporter stated that the water used in irrigation was coming through the drainage tube for twenty-four hours after the operation. I know of no instance where irrigation water remained in the peritoneal cavity that long. In cases of this character where I have used drainage —as my experience widens I drain less, but there are cases where you are compelled to drain—I have noticed that the irrigation water did not come through the tube or gauze very long after the patient was put to bed, but the discharge was of serum and blood from the torn structures.

The largest tubes or tumors are not always the most difficult to remove. I have removed pus tubes, as large as the one exhibited, where enucleation was comparatively easy, and have removed tubes much smaller where the enucleation was very difficult. I do not understand how such tough adhesions could form in such a short space of time, and I am sure they must have existed before the rapid dilitation of the uterus. The adhesions of a so-called inflammatory exudate and re-

cently formed peritoneal adhesions are, generally speaking, easily separated.

Dr. W. C. Dugan: I think the specimen teaches a very valuable lesson—that delay is dangerous in such cases. My experience with pyo-salpinx is that they are most all complicated with cystic ovaries. To discuss the case further would be to repeat what Drs. McMurtry and Wathen have stated, as they covered the ground.

LEUCOCYTHEMIA: APPENDICITIS.

Dr. A. M. Vance: I was called on the 29th of last November by Dr. Leachman to see a boy who had had since last March an enlarged spleen. The patient was about seventeen years of age and his spleen had grown gradually since it was first observed in the early part of March until the time I saw him, when it was enormous.

I was called to the case to stop hemorrhage from the nose, which had been going on for forty-eight hours and the boy was pretty well exsanguinated, showing his grave condition. Dr. Cheatham saw the case and the boy was still bleeding although I had plugged the nose from the front and posteriorly. The boy eventually died of hemorrhage from the whole alimentary canal. He passed large quantities of blood per rectum and threw it up from the stomach—much more than could possibly have come from the nose. Diagnosis had been made as Leucocythemia.

A post-mortem was obtained and we secured the spleen, liver and supra-renal capsule. The spleen and liver are exhibited for your examination. You will notice that both organs are enormously enlarged, the spleen being over a foot in length and weighed when removed nearly twelve pounds. The kidneys were also very much enlarged. Dr. Louis Frank has made several microscopical sections of both the liver and the spleen, which I have asked him to bring here to-night for your inspection, and upon which I hope he will give us some further information with the result of his repeated tests.

I was called by Dr. Baker on December 16th to see a man thirty-two years of age, a butcher, who had been suffering for twenty-four hours only with all the symptoms of acute appendicitis. He gave the history of having had some bowel trouble always preceded by diarrhœa, as was also this attack, but had never before been laid up. The man had a temperature of of 103.5° F. when I saw him and had had one rigor a few hours before. His pulse when Dr. Baker was first called was only 59 to the minute, and when I saw him, despite his fever, it was 72, which is a very curious element in the case. I advised and performed immediate operation.

I exhibit here the specimen removed, which is a very curious appendix. It was on the verge of perforation; was adherent to everything adjacent, and particularly to the omentum which had formed a sort of wall or sac around it. When I first introduced my finger and pulled up the appendix I thought it was very much enlarged. The appendix was tied off at the junction with the cæcum through reasonably good tissue; all of the omentum which came in contact with the appendix was removed; the wound closed with silk worm gut, a glass drainage tube being left in twelve hours. The man made a rapid recovery. I think if operation been delayed twenty-four hours longer, he would have had general peritonitis.

DISCUSSION.

Dr. Louis Frank: The exact measurements of the liver and spleen exhibited by Dr. Vance I do not remember, but they were much larger at the time of removal than at present, the liver especially having become considerably macerated. As yet I have not examined the kidneys nor the supra-renal capsule.

In the spleen, however, I found upon microscopic examination what appeared to be white infarctions, and with these some spots that appeared to be cheesy in character, those latter I found instead of being degenerated tissue were made up of dense connective tissue. The capillaries and larger vessels of the spleen were found to be filled with white blood corpuscles and no red ones at all. In the several sections made not a single red blood corpuscle could be found. In the liver there is some increase in the connective tissue which is due to round cell infiltration. Polynucleus cells being also found giving a true new connective tissue formation, caused probably by cells that had found their way through the thin vessels into this connective tissue. Also the capillaries between the individual cells

were very large, these cells being crowded to the sides and the capillaries filled in with white blood corpuscles. The cells in sections of the liver examined had undergone no degeneration at all, as we might expect to find from pressure, they were perfectly normal cells of the same size that we have in ordinary live tissue. The liver was rather soft when removed, a great deal more so than we expected to find. The spleen when removed weighed about eleven pounds, the liver a little over ten pounds. An examination of the blood taken from this patient was made by myself, also by Dr. Weidner, some weeks before death, and then the proportion of white to red blood cells was as one to two. This is very high, the ordinary proportion being one to six hundred. I have no doubt if the blood had been examined just before death the proportion would been even more than this.

DISCUSSION.

Dr. W. C. Dugan: I saw the patient referred to by Dr. Vance in the latter part of February or early in March, and he then had a large tumor extending down into the pelvis. The question of diagnosis in these cases is one of great importance. It is very simple when you examine for the notch, which is oftentimes overlooked. The notch in which the large vessels enter is always very marked and can be easily outlined. When this boy came to me the question was whether he was suffering from leucocythemia, or whether it was malignant disease. I was inclined to the diagnosis of leucocythemia and sent him to Dr. Simon Flexner; he being absent from the city at the time, his brother made an examination of the boy's blood and found the white corpuscles one to two. Of course when he made this report I decided it was not malignant in the sense that we usually use the term "malignant," and refused to have anything further to do with the case in a surgical way and he went back to his physician.

About a year and a half ago I was called by Dr. Larrabee to see a lady in this city who had a very large spleen, in fact one which nearly filled the abdominal cavity, and was asked if I thought it advisable to remove it. At first I thought very favorably of its removal—until I went home—then I consulted all the authorities on the subject that I had and found that there was no case on record that had recovered after such operation, and of course, I changed my mind. I made a post mortem in this case removing the spleen which weighed between seventeen and nineteen pounds, if I am not mistaken. In this case there was no apparent change in the liver or any other organs of the body. There are three forms of this disease; one form involving the medullary canals of the long bones; another involving the lymphatics, and the third involving the spleen. The pathology of the disease remains to be written. Such cases are universally fatal, most of them dying as did this boy, by hemorrhage. This disease is not so rare after all. I know of four cases in this city within the last two or three years, and doubtless there are others.

Dr. W. H. Wathen: I wish to emphasize the practical value of conservatism in the treatment of the case reported by Dr. Dugan. Surgery of the spleen has been very successful in many particulars considering the apparent difficulties with which we have to deal. Probably the desire to operate upon enlargements of this organ has caused men to perform the operation where it was contraindicated. There are probably very few surgeons engaged in abdominal work who appreciate practically the fact that there is no case, at least no well authenticated case, where extirpation of the spleen for leucocythemia has been successful. For that reason I say this case is especially opportune in bringing out this feature so that the profession may understand it.

Dr. J. W. Irwin: I regard these cases more in the light of medical curiosities than anything else. I have seen two cases of this nature within the last twelve years. The first was in an adult who lived in a malarious part of the country, and it was thought for a long time that he had an "ague-cake." When the case came under my observation, the spleen filled nearly the whole of the abdomen, giving the appearance of a person in the last stages of ascites. Of course the patient died and a post mortem was held; the spleen was found to weigh twenty-nine pounds; the liver weighed eight pounds.

The next case which came under my observation was in this city less than one year ago, in a child under one year of

age which was the offspring of healthy parents. The child had become so thoroughly anæmic that two or three physicians had been called and none of them would venture a diagnosis. One physician said it could not be cured, another said he did not know what the disease was. I made a careful examination and found the spleen very much enlarged, with apparently no enlargement of the liver. The child was profoundly anæmic and died. I am sure that the spleen filled three-quarters of the abdominal cavity, it was so enormously enlarged, notwithstanding the tender age. All that I could do was to prognosticate death.

Dr. J. M. Ray: Two years ago last September an Irish lad about nineteen years old consulted me about his nose. He was a great politician and on election night had been hit on the bridge of the nose. The result was a sinus leading down to the septum and on probing I found a piece of necrosed bone. By anterior rhinoscopy an accumulation of pus was found between the bone and periosteum of the septum. I made a small incision into the pus cavity and let out quite an accumulation; hemorrhage was very slight at the time. That afternoon I was out and on returning about 6 o'clock I found the entire office floor covered with blood. My servant told me that the gentleman whose nose I cut in the morning had returned and his nose had bled so furiously that he fainted and a carriage was called to take him home. I immediately went to see the patient and found him with the most persistent case of nosebleed that I ever saw. I plugged it behind and in front. Then the blood would come out of the sinus. I worked with him for three or four hours, and at last succeeded in stopping the flow. He came to my office again after four or five days and I then began to investigate the cause of the hemorrhage. He told me that at one time he had a tooth extracted and had considerable hemorrhage.

The case then passed from under my observation until the following summer. In the meantime I understand he remained in very good health. The following summer he consulted me for intense vertigo and deafness. In testing his hearing the tuning fork pointed to it as of nervous origin. He gave me the history that the deafness had come on suddenly about a week before I saw him. This of course put a new aspect upon the case and I began to further investigate, still did not make a diagnosis. I noticed at this time that he did not wear the top button of his pantaloons fastened, and upon questioning him he said that his abdomen seemed to be swollen so that he could not button his clothing. I then made an examination of the abdomen and found the spleen very much enlarged. I was led to make an examination of his eyes by the profound deafness and enlargement of the abdomen. Upon examination with the ophthalmoscope I found a typical illustration of a cut in Jaeger's Atlas of Ophthalmology, a pale straw colored fundus covered with peculiar patches and hemorrhages. Both eyes were involved, yet the sight seemed to be perfect. From these symptoms I made the diagnosis of leucocythemia. Subsequently I believe both Dr. Weidner and Dr. Frank examined the blood and pronounced the trouble leucocythemia. The man went on from bad to worse, growing weaker and weaker, and on several occasions had fallen in attacks of vertigo. He came to me one day and said he had something on his hip that he would like to show me. Upon examination I found an immense hæmatoma, probably as large as your doubled fist. In his vertigo he had fallen and said this lump appeared on his hip afterward. This disappeared in a few days and eventually he began to bleed from the gums and from the throat. In the meantime his abdomen had continued to increase in size until he was as large as a woman at the ninth month of pregnancy; distended veins running over the abdomen; his feet also became so swollen that he could not walk during his last two or three weeks of illness. Hemorrhage continued from the gums, then from the nose, then he began to vomit blood, then purge blood, and finally he died. I tried to obtain a post-mortem in this case, but was unsuccessful on account of objections on the part of his family.

While this patient was coming to me I saw in one of the medical journals arsenic recommended in cases of this character. I prescribed this drug which gave him more relief than anything else. He grew stronger and seemed to suffer less inconvenience from distension of the abdomen while under Fowler's solution.

Dr. L. S. McMurtry: The second specimen exhibited by Dr. Vance is a very in-

teresting specimen to me, and the subject is one that I do not think has ever been thoroughly discussed in the Society. We have had several cases reported but I do not believe the subject has ever been taken up methodically and discussed as it ought to be on account of its importance. I remember two years ago this winter I attended a meeting of the Surgical Society and reported two cases of abdominal section for appendicitis, with recovery. In the discussion that evening one of the fellows implied skepticism as to the existence of such a disease and expressed opposition to treatment by operative interference. I believe at that time there had not been a single operation for appendicitis done in Louisville. Since that time the operation has been done many times in this city; it has been done by Dr. Satterwhite, by Dr. Dugan, by Dr. Vance and by others. It is the most common cause of peritonitis in the male, and if we will take the Health Officer's reports as they appear in the daily paper every Monday morning, it is the exception not to find one, two or three deaths reported from peritonitis, which means that there was no diagnosis made because peritonitis is of itself not a disease. In cases of appendicitis we have yet to improve in regard to early operation. Now, this specimen exhibited to night had adhesions around it, but there was no extensive suppuration, and the operation was done before the pulse had run up and before the system was saturated with septic products.

There is one particular fallacy in regard to appendicitis that I would like to call especial attention to. We often hear the argument against operative measures, that one case or perhaps a dozen cases has been treated by conservative measures,—opium, poultices, etc.,—and recovered. And one case may be reported by five or six different physicians as having recovered, which is operated upon by the seventh physician. This will go on record as six cases of recovery from appendicitis without operation when the patient has never recovered and has been operated upon by somebody else. These statistics are used as an argument against operative interference when the patients have passed into other hands for operation.

A patient may have recurrent attacks of appendicitis and we never know when perforation will occur. I recently operated upon a little girl six years old with general suppurative peritonitis, where the appendix had sloughed off and came out with the irrigation water. The operation was done on Saturday at eleven o'clock and the girl was at school on Wednesday preceding. We never know when we have a case of this kind and the practical point is not only that operative treatment is the proper procedure, but we must take one step forward and let the surgeon see the cases sooner and let the operation be done sooner. If it is done early the majority will recover. The success of the operation in the majority of cases depends upon the time elapsing after the initial symptoms of the attack, until the operation is performed. I think the Society can with advantage discuss this very important subject and formulate something like definite data for operative interference—those symptoms which indicate immediate operation. In the case reported by Dr. Vance it was operated upon right in the golden moment. Only to-day a case came under my observation where the patient was passing berry seeds, etc., through an abscess that had broken through the abdominal wall from the appendix, indicating how common this trouble is and what risks are incurred by delay in operating. The operation when skillfully performed is not, of itself, dangerous; whereas delay with uncertain diagnosis is always dangerous in intra-abdominal diseases.

Dr. W. H. Wathen: This case illustrates the simplicity in operating successfully in some cases of peritonitis of appendicular origin. The dangers in operations of this character with an experienced surgeon are practically nil; but in other cases the operation is very difficult, and the results are often necessarily fatal because of extensive involvment of the peritoneum and abdominal viscera. This is a subject that has been discussed and written about *ad nauseam*. Every leading surgeon is practically familiar with the literature of the subject; and while there are some very beautiful results, the enthusiasm of some surgeons has pushed the pendulum too far and during the last two years it has begun to swing back. The man who does not go too far in either direction would probably be the safer man for this kind of work. Again, it is impossible to always tell whether the trouble is appendicular. Every surgeon of experience in abdominal work has observed cases in his operations

that have been diagnosticated appendicitis, where the appendix was not involved and the case was one of peritoneal trouble of some other origin. Again, there is no denying the fact that there are many cases where the subjective and objective symptoms plainly indicated appendicitis more marked than in many cases operated on, where the patients have recovered and are now, years after the attack, apparently well. I know of several such cases. No doubt there are many cases where death has resulted because the surgeon had not seem them sufficiently early—because of delayed operation. On the other hand there are cases that are not surgical.

Cerebral Concussion.

Miles (*Boston Med. and Surg. Jour.*) reviews the old theories of so-called concussion of the brain and concludes there may be a fatal injury to the head in which there is no appreciable gross lesion to the brain substance, directly or through its membranes. He does not consider the old theory of vibration tenable owing to the fact that the brain does not exactly fill the cavity of the skull; that there is between it and the skull a certain amount of cerebro-spinal fluid, and that the membranes fix the brain so thoroughly in position that any considerable displacement would be evidenced by lacerations. Nor does he consider that multiple hemorrhages are sufficient to account for the many and varied symptoms of concussion. He believes, however, that the symptoms are due to a derangement of the cerebral circulation, and he shows by experiments on animals that a severe blow on the head will cause very marked changes in the general circulation. The symptoms, therefore, are due to a profound disturbance of the circulation in the brain producing a condition of anæmia, which is due to stimulation of the restiform bodies.

The mechanism of the injury he considers to be: a blow is dealt to the cranial wall; surrounding the point of impact the skull is depressed; following the cone of depression from the area into which this cone bulges, the cerebro-spinal fluid is forcibly expressed at the opposite cone of the axis of percussion, forming a cone of bulging, which accommodates most of this displaced fluid; these cones, however, are only of momentary existence, the elasticity of the skull permitting the bone to return at once to its *status quo;* at each point, therefore, is formed a vacuum the result of which is that the blood vessels of the membranes and brain substance at this place are left for the moment unsupported, and rupture. This cone of bulging may be regarded as the true contrecoup, but Miles is so skeptical as to consider that most of the so-called fractures by contrecoup are really produced by direct violence; the patient, being struck on one side of the head, strikes the other side in his fall producing a fracture. A blow upon the frontal region or vertex will naturally produce the cone of bulging at the base of the skull and, therefore, the fatal cases of concussion are likely to be associated with peribulbar lesions.

By further experiment he finds that a sudden aspiration of cerebro-spinal fluid leads to extravasation of blood, but slow aspiration does not. A hard blow on the skull after the blood has been so removed gives a much less destructive lesion than when the fluid has been left in its normal position.

He concludes that the phenomenon called concussion of the brain is the result of a temporary anæmia of that organ; this anæmia is the reflex result of stimulation of the restiform bodies. These are also stimulated by the wave of cerebro-spinal fluid, which rushes through the aqueduct of Sylvius and the foramen of Magendie, and from the subarachnoid space of the brain to that of the cord, when a severe blow is dealt over the skull. This wave, in accordance with the laws of hydrostatics, would disturb the equilibrium of the ultimate nerve cells throughout the nervous system. The hemorrhages found throughout the brain substances and on its surface are to be ascribed to the recession of the cerebro-spinal fluid which naturally supports the blood-vessels. The small hemorrhage found in cases of so-called concussion, are rather an index of the force producing the injury than the cause of the resulting phenomenon.—*Abst.*

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, FEBRUARY 4TH, 1893.

EDITORIAL.

AN AGNEW MEMORIAL.

It is difficult for a community, at any time, to accept the decree that the work of a man like Dr. Agnew is done; that for one so loved for his wisdom, the purity of his life and unselfish devotion to his duty there was not much yet to do, and more time alloted to do it in.

By the right of great powers and many virtues, and the beneficent uses made of them, Dr. Agnew's memory should be secured to other generations than that to which he belonged. He did too much for those among whom he lived and to whom he rendered unselfish service, for them, without discredit, to fail to build some tribute to his memory—something to further the great causes to which he devoted all the energies of his mental and moral faculties; something typical of his noble example, of the purity and courage of his life, of his unselfishness to his profession and to humanity.

It is now, while the memory of his intense manliness and his effective work are warm with us, that steps should be taken to provide a memorial to a name associated with all that is best in the healing art, that will advance the work he loved and performed in so masterly a manner. Let it be one that will speak longer and more fittingly of him than could the most careful and eloquently written biography. It should realize what he did for the suffering and the grateful love they bore him, the expression of which can never be carved in marble nor traced in bronze.

There is no more splendid characteristic of his life than his unselfish devotion to the welfare of his fellow beings without regard to creed, condition or social position. He was ever in readiness for service. Few men in professional life have lived so unselfishly. The profession he chose as his life work is one primarily of duty. His work was a love, a religion which he served with unswerving faithfulness. Through all the busy years of his life he kept in it the enthusiasm of youth. His chief counsellor was an enlightened conscience.

It requires great courage to be a great

surgeon. He possessed that and more. His was not the boldness of greed, nor the recklessness of narrow ambition, but the fearlessness born of great convictions and tender human sympathy. It was a chivalric courage that made the timid braver in his presence. In his genial, kindly temperament, in the variety of his excellencies he was the ideal gentleman and physician realized.

His greatness was in disciplined strength rather than in specially inherited powers. He created his own opportunities and wisely made use of them. He may not have possessed that indefinable something akin to madness, which men call genius, but he was the embodiment of intelligent power—crowned withal with Christian humility and charity.

He wove his name and work closely into the interests and memory of the great community he so faithfully and unselfishly served. His was a ready sympathy with every form of suffering, and was manifested by acts rather than by words—the daily deeds of one hand unnoted and unknown to the other. No taint of insincerity marred his character. "He attained to the advantage of bringing every man of his acquaintance into true relation with him. No man thought of speaking with him, or putting him off with any chat of markets or reading rooms. But every man was constrained by so much sincerity to the like plain dealing."

Whatever may be the form of the memorial, those who knew him, one and all, will have some honored characteristic to recall. Those who were his students—his boys, as he was wont to call them—will ever preserve a fragrant memory of the natural dignity of his thought and deportment, and will treasure the lessons he taught with such rare impressiveness and rarer modesty. And always they will feel the stimulus of his great energy and courage, and will bear with them some impress of his strong personality.

In all that ethically concerned the profession, he had few peers. As an adviser he gave of the best he had. A conscientious consultant, he had no jealousies to warp his opinions which were always characterized by frankness.

As a writer he was clear, concise and vigorous. Bringing together the knowledge and experience of all medical science he subjected it to the rigid scrutiny of his mature judgment and, adding to it much of proved value in his own experience, gave to the profession by far the best text book of modern surgery. His work is not that of a mere copyist or translator, but has a distinct, strong individuality, and will furnish the foundation material for many a coming "treatise" on surgery.

But it is not as an author that Dr. Agnew's name will live the longest. The marvelous development of medical science, in all its departments, must inevitably render much of what he wrote obsolete. Moreover it is Dr. Agnew—the man, the skillful surgeon, the sympathizing friend, the helpful counsellor, the modest philanthropist, the unassuming Christian gentleman—whose virtues are to be perpetuated in some form worthy of the man.

The men of other countries, who seek home in ours, honor alike the country of their birth and that of their adoption, when they erect upon our soil memorials to the genius of their fatherlands. We erect on our public squares costly monuments in memory of martial spirit and martial genius. Why should we forget one of the noblest types of American private citizenship, who devoted time and talent to healing the wounds war made, and who spent his unselfish life in endeavoring to relieve the suffering of others?

The establishment, in connection with the University Hospital, of a children's ward has been suggested as a suitable form of memorial to our great surgeon. For various reasons this is a fortunate suggestion.

For many years Dr. Agnew's name was intimately associated with that of the University of Pennsylvania. There he gained laurels for himself and added lustre to the fame of the Institution. But most especially was it there that the influence of his strong personality and clear scientific teachings made the deepest impression on the profession.

The many thousands of University Alumni should see to it that any memorial of a friend and teacher so revered, should in some measure be adequate to his honor. In this form also it would be assured speedy accomplishment, and that without undue expenditure for sustaining *professional* philanthrophists.

Nor need the movement be confined to the Alumni of the University. Hundreds of public spirited men, who knew and loved Dr. Agnew in life and appreciated the stalwart manliness of his character, have a common interest and pride in his name and fame. It would be their pleasure, and duty as well, to aid such a work of love, honor and gratitude.

It is to be sincerely hoped that immediate and organized effort will be made by the old students and friends of the great surgeon and teacher, to erect some fitting tribute to his memory—such as will not alone honor his name, but be one of the prides of our great city. If it be not a children's ward or an addition to the University Hospital, let it be something else worthily representative of the meaning his life and work had for his fellow's—wide-reaching in the spirit of its benevolence.

TRANSLATIONS.

INFECTIOUS ERYTHEMAS.†

Hutinel has carefully investigated the erythemas attendant upon infectious diseases as occurring in his service at the Children's Hospital. The characteristics of these cutaneous manifestations studied from different clinical points of view, the pathological anatomy and the miscrobiology are essentially the same, whatever may be the primary disease (typhoid fever, diphtheria, measles, scarlatina, angina, etc.,) and the author has thus been enabled to group them into one general pathogenic study. The infectious erythema may follow in the course, at the decline or during the convalescence of the preceding disease. Clinically it is characterized by macules, or blotches, more or less extended, but slightly elevated and transient, and having at times a marked tendency to become ecchymotic. The eruption commences at the wrists, the elbows, the knees, the malleoli, on the upper part of the buttocks, rarely on the neck. It remains at times fixed in these points of election, but ordinarily it invaded the back of the hands and the fingers, the fore-arm and arms, the dorsal surface of the feet, the front of the legs and thighs. The back, breast, and abdomen are more rarely invaded; the face only exceptionally. The progress of the eruption is usually centripetal. Its forms appertain to the different varieties of polymorphous erythema: linear, circular, papular, measly, scarlatiniform non desquamative, scarlatiniform desquamative relapsing. At times purplish spots are associated with the polymorphous eruptions. In spite of the apparent variability of their forms, a variability that depends very much upon the manner in which the skin reacts in the different subjects to the irritating agent, these eruptions have common characteristics. The different eruptive forms may co-exist, follow each other or transform themselves in the same patient; the confluence or the limited extent of the eruption does not have any connection, slight or great, with the gravity of the general phenomena. The erythematous patches are generally symmetrical, transient, and disappear without leaving any trace. They are never associated with a similar eruption upon

†Translated for The Medical and Surgical Reporter, by W. A. N. Dorland, M. D.

the mucous membranes; but, on the contrary, often there exist ulcerous lesions upon the lips, mouth, pharynx, etc., to which Hutinel attributes considerable importance as the points of entrance of the secondary streptococcic infection which becomes the pathogenic cause of the infectious erythemas. In *typhoid fever,* in numerous cases otherwise benign, Hutinel has witnessed a veritable epidemic of infectious erythema, grave and even fatal in some cases. The eruption always appeared after the second week, either in the course of the descending oscillations, or after the definite fall of the fever, or at a period more or less advanced in convalescence. In *measles* the frequency and the gravity of the eruption appeared favored by the atmosphere of the hospital and by the coëxistence of purulent bronchitis and broncho-pneumonia with streptococci. The erythema in *diphtheria,* noted by most of the authors, appeared more commonly in children than in adults. It showed itself either in the beginning of the disease, in which case it was generally benign; or at an advanced period, where it was much more serious and often fatal. In these cases there is almost constantly noticed lesions of the lips (fissure, pseudo-membranous exudate,) of the mouth, (ulcerations, diphtheritic false membrane,) of the nose and of the throat (reappearance of the false membrane with streptococci, the specific bacillus of diphtheria having often disappeared.) Hutinel also noticed secondary infectious erythemas, benign or grave, at the close of *scarlatina*; in the course of certain anginas with streptococci (all followed by recovery,); in the course of certain choleriform diarrhœas; in affections of the urinary passages; in intestinal lesions; in pyogenic infections, etc.

The malignant forms of the infectious erythema generally accompanied grave phenomena; livid face, pinched nose, stupor, emaciation, tendency to cyanosis, thermic elevation followed by subnormal temperature, then finally by hyperpyrexia, slight troubles of the intellectual functions, profound prostration, vomiting, green fetid diarrhœa, scanty urine at times albuminous. Certain symptoms predominate according to the nature of the primary disease: gastro-intestional phenomena, prostration, and thermic disturbances in typhoid fever; respiratory trouble and broncho-pneumonic manifestations in measles; puffing of the face, albuminuria, cardiac troubles in diphtheria. At the autopsy the liver is found enlarged and fatty, the spleen a little hypertrophied, Peyer's patches and the mesenteric ganglia tumefied, but slight renal lesions, and concomitant alterations of the respiratory organs common to all of the infectious diseases. The blood is brownish black, but does not contain microörganisms. These are not found either in the affected skin or in the hepatic tissue. There is therefore room to admit, in the absence of micro-organisms, rather a poisoning of the blood and fluids by soluble products, a poisoning comparable to that which plays so important a rôle in diphtheria. The *treatment* should be especially prophylactic; antisepsis of the mouth, nose, and pharynx, isolation of the patient, hospital hygiene, etc. (*Archiv. gen de med.*, Paris, Sept. and Oct., 1892.)

CATARRHAL NEPHRITIS IN SYPHILIS, TUBERCULOSIS AND LEPROSY (LEPRA).†

Lancereaux states that these diseases, which resemble one another as much in their origin as in their anatomical manifestations, may present in the course of their evolution three varieties of alteration in the kidneys, each having a different signification, which it is important not to confound. In the first place they directly influence these organs and determine in them disorders identical with those which are produced in the viscera; thus syphilis produces in them gummata and a circumscribed interstitial nephritis; tuberculosis, tuberculous lesions *en masse* starting at the Malpighian pyramids, or disseminated tubercules; leprosy, the leprous nodosities, or a cirrhotic nephritis.

In the second place, in some cases there

†Translated for the MEDICAL AND SURGICAL REPORTER by W. A. N. Dorland, M. D.

follows in an advanced stage of these diseases, a peculiar degeneration of the vessels and renal parenchyma designated by the name of *amyloid,* or better *leucomatous, degeneration.* Each of these diseases, finally, at some time in the course of its evolution gives rise to a nephritis similar to the pyretic, and especially to the epithelial or catarrhal nephritis, which has at times been recognized under the name of the *great white kidney.* But these three classes of affections, clearly distinct, as much by their localization as by their clinical manifestations and course, do not have the same bond of union with the diseases in the course of which they show themselves. Those which compose the first series, and whose localization is in the vessels and the connective-tissue stroma, are associated manifestly with the general disease, syphilis, leprosy, or tuberculosis. The lesions which make part of the second series, very different in nature, characterized by a hyaline deposit in the tunics of the vessels, belong rather to the state of decay of the organism caused by the primary disease; those of the third category can no more than these last, be under the direct defendance of these diseases, because of their localization in the epithelum,—entirely different from the fibro-vascular localization proper to each of the diseases in question—their evolution and their mode of termination.

The catarrhal nephritis of syphilis, leprosy and tuberculosis is similar to the nephritis of pregnancy and that of pyrexia in that it is only the indirect effect of these diseases; or rather that it seems to find in them the proper elements for its development. Unfortunately just what these elements are is at present unknown, but if a comparison is made between this and the nephritis of pyrexia, which has the same anatomical localization, it is but natural to suppose that they might have a similar origin and associate themselves with the secretion of toxines created by the specific disease. This is a purely hypothetical view, it is true, but it does not destroy the distinction which has been made between the forms of nephritis occurring in the course of syphilis, leprosy and tuberculosis.

The catarrhal nephritis observed in the course of these diseases begins at an early period of their evolution, in the first or second phase rather than in the last, as distinguished from the specific nephritis and so-called amyloid degeneration. In syphilis, for example, the catarrhal nephritis shows itself during the secondary period, rarely later; and always in tuberculosis and leprosy this affection appears before the last stage.

The onset of this nephritis, usually quite abrupt, is manifested, following a fatigue or a chilling, by a diminution in the quantity of the urine and by the appearance of an œdema, at first limited to the face, scrotum and limbs, but quickly becoming general. At the same time is experienced a tired feeling; soreness and weight, if not pain, in the lumbar region; and, in a certain number of cases, a febrile state, which may be unrecognized. This group of symptoms conduces to an examination of the urine, which is small in amount, cloudy and colored, of a reddish hue, with a specific gravity of 1020 or over, giving with nitric acid and heat an albuminous precipitate in the form of large flakes of a milky whiteness. The deposit, as shown by the microscope, is composed of altered epithelial cells, hyaline or epithelial casts, leucocytes and, more rarely, red globules. The swelling of the face and the anasarca persist, there is a gradually increasing pallor of the skin, the anemia becomes excessive, appetite is lost, digestion is disordered, sleep is disturbed, there is a loss of strength; then in some instances the serus extravasations limited to the subcutaneous cellular tissue, invade the pleural, peritoneal and pericardial cavities and gives rise to dyspnea in proportion to the degree of effusion.

Such are the phenomena which mark the first phase of the catarrhal nephritis in question. To these are added, at the expiration of a variable period of time, the symptoms of uremia which characterize the second stage. Vomiting now follows immediately after the ingestion of food; it is composed in part of this and partly of a scanty fluid, grayish or slightly greenish in color, and is repeated ordinarily several times in the day. It is nearly always accompanied by constipation, but at times the stools are liquid, whitish or greenish, passed readily and without acute pain. Under other circumstances nervous symptoms make their appearance, often grave enough to compromise life. There is shortly developed an intense dyspnea, if not a most painful orthopnea,

frequently accompanied by severe pains which the condition of the thoracic viscera will not account for. Insomnia and an intense cephalgia of the frontal, temporal and occipital regions appear, compared by the patients to a compression of the entire head similar to the sensation produced by a heavy helmet. Convulsive seizures having all of the characteristics of eclampisa, and in some cases oft repeated, sap the strength of the patient, and delirium and coma, more of less profound and dangerous, may be noted. The urine now is less abundant and but four or five hundred grammes may be passed in the twenty-four hours. The proportion of albumin is considerable, but the quantity of urea and salts is diminished.

The kidneys under these circumstances present alterations scarcely different in spite of the diversity of the specific diseases. They are tumefied, elongated and swollen; their volume may be double the normal. Their consistence is soft, at times unctuous, and their color sometimes violet and whitish, sometimes dark-grayish dotted with disseminated white spots. The two colors show clearly upon the surface of a section; for if the medullary substance is simply violet, that of the pyramids presents a whitish lardaceous aspect quite distinct. Moreover the excretory tubes which constitute the pyramids, as well as the vessels that are distributed to them, are not modified; while the secretory tubes, which enter into the composition of the cortical substance, are always profoundly altered. These tubes, in truth, enlarged and distended, have their lumen narrowed by the tumefied epithelium; this epithelium is infiltrated by proteid and fatty granulations; the cells are deformed, or even reduced to fine debris, which together with the hyaline cylinders, obstructs the uriniferous tubules and places an obstacle to the passage of the urine. The glomerular epithelium is ordinarily less modified. As to the vessels and connective tissue stroma, they do not present any appreciable abnormality.

The diagnosis of this form of catarrhal nephritis is generally easy. It is based upon the diminution of the urine—its color, density and microscopic characteristics and also upon the anasarca and most marked albuminuria. This nephritis, which most writers have confounded with the specific nephritis proper to each of the diseases in question, is distinguished clearly from the latter both by its anatomical localization, and by its clinical phenomena. Effectively, the essential seat of the alteration is the secretory epithelium in one case, the vessels and the connective tissue-stroma in the other; localizations so different can never arise from the same cause. The lesion, always partial and asymmetrical in the nephritis which depends directly upon syphilis, tuberculosis, and leprosy, is generalized and symmetrical in this catarrhal form; the albuminuria is slight and the anasarca ordinarily absent in the former, whilst the albuminuria is abundant and the anasarca considerable in the latter. Thus, none of the symptoms proper to these affections are similar, and, in consequence, it is not possible to confound them, or to attribute to them a common origin. It is much more difficult to establish a diagnosis between this form of catarrhal nephritis and amyloid degeneration of the kidneys. However, the abundance of the urine, its faint color and low density, the absence of hyaline casts, are especially characteristic of the leucomatous nephritis, and suffice to distinguish this affection from the nephritis in question.

The prognosis of catarrhal nephritis in these subjects is always grave, since to a disease very serious in itself is added a condition which constitutes a true danger. The method of combating the symptoms of renal inadequacy varies with the stage to which the disease has advanced. Early in the course dry, or even wet, cups are indicated over the renal region, together with stimulating frictions of the surface followed by a hot bath. An exclusive milk diet is essential. If these simple measures will not suffice, the tincture of cantharides, in five or six drop doses may be administered. Should uremic complications appear, drastic purgatives are urgently indicated. While treating this complication of the original disease, whether it be syphilis, tuberculosis or leprosy, it is not necessary to pursue the specific treatment of the primary disease.—*Le Bulletin Medical*, Jan. 11, 1892.

Little Sister—"Mamma says Mr. Nexdoor is sufferin' from a complication of diseases."

Little Brother—I guess that's so. I've seen three different doctors go in there this morning."—*Good News.*

The Treatment of the Pedicle in Abdominal Hysterectomy.*

Boulengier mentioned the following new methods of operations for Myoma in a discussion at the Belgian Gynecological and Obstetrical Society.

1st. The method of Leon Desguin at Antwerp, who fastened the integument beneath the elastic ligature around the stump and holding this in place by the pedicle pins, protecting the ends by gauze compresses.

2nd. The treatment of Lauwers of Courtrai, who sometimes treats the stump extra-peritoneally by applying a ligature which remains in situ (24 or 48 hours,) until hemorrhage is thoroughly controlled; the ligature is then removed, the stump allowed to retract, and the abdominal wound closed. He reports three cases with rapid recovery.

3rd. The method of Rouffort of Brussels, is total extirpation; he removes the stump through the vagina and controls hemorrhage by clamps.

4th. De Baisieux, of Lowen, uses an elastic ligature which is united with silk threads; the long end of the silk is allowed to come out of the lower angle of the wound, while the stump is allowed to drop back into the abdominal cavity. This has been previously covered by iodoform gauze, the end of which is also allowed to pass out at the lower angle of the wound. Two or three days after the operation this gauze is removed and replaced by a new piece (up to the second week.) After five or six weeks the elastic ligature is withdrawn by the silk thread which has been allowed to hang out. Three operations have been performed in this manner with success.—*Presse Med. Belge,* XXIV, 12. 1892.

Subcutaneous Injection of Fowler's Solution.*

Popow speaks of two cases of malaria successfully treated by subcutaneous injections of Fowler's solution.

1st. An old man whose history is given in detail, and who seemed to be suffering from chronic malaria, and in whom the treatment with quinine had been unsuccessful. The condition of the gastro-intestinal tract prevented the administration of arsenic, so the author concluded to try subcutaneous injections of the above named solution. The first three days there was a dose of 0.4 ccm. of the undiluted solution. The following three days, the dose given was 0.6 ccm., and five days later 0.8 ccm. and then three days after 1.0 ccm. Besides this he received later for six times 0.8 ccm. and twice 1.0 ccm. Almost immediately after the first few injections a marked improvement was noticed. The temperature became normal, the former dyspeptic symptoms disappeared, the liver which had been enlarged began to contract, jaundice disappeared, as did also the œdema which had been present.

The second case was that of a young girl. The diagnosis was made by Professor Sacharjin, of masked malaria and chronic anæmia. An examination of the blood showed three millions of red blood corpuscles in 1 c. mm., and 75 per cent. of hæmoglobin. The patient received fifteen injections of the undiluted solution, 4 times 0.4 ccm., twice 0.5 ccm., 3 times 0.6 ccm. and 6 times 0.8 ccm. The result after this treatment was that the violent pains in the head disappeared, the enlarged spleen could no longer be detected by superficial palpitation, and the general condition was good. The examination of the blood revealed four millions of red blood corpuscles in 1 cmm. of blood, and 90 per cent. of hæmogolobin. The patient increased in weight.—*Medizinao* IV, 1, pp. 1–5. 1892.

Contributions to the Total Extirpation of Uterus per Vagina in Malignant Disease.*

Rossier of Basel, reports a hundred cases of carcinoma of the uterus, seen at Fehling's Clinic, from June, 1887, to the end of 1891.

Of these, 25 vaginal hysterectomies was performed. In two it had to be finished by combined laparotomy. After two years there were 23.8 per cent. free from return. There was but one death among the number operated on in which the post mortem showed peritonitis and carcinomatous degeneration of the retroperitoneal glands. R. places great stress upon early diagnosis and operation as a means towards a cure.

Hepatic Insufficiency in Mental Diseases.—Hepatic Insanity.†

According to Klippel, among the mental diseases in which hepatic alterations have been observed at the autopsy, or during life by the process of modern biochemy, one group is formed by the affections where the hepatic lesion is secondary (sometimes inactive as in general paralysis, sometimes influencing the psychical troubles as in alcoholism); another group includes those cases in which the hepatic lesion is primary and appears to provoke the alienation; this is hepatic insanity. The hepatic lesions of general paralysis are the nutmeg liver, red atrophy, patches of decoloration, fatty degeneration, cirrhotic and vaso-paralytic congestion (decolorized patches, dilatation of the capillaries with hemorrhages, diapedesis, cellular compression and cirrhosis). The hepatic lesions of alcoholism maintain, perhaps, the delirium in the cases where this persists notwithstanding the suppression of alcohol in the cases where the brain is but slightly injured. The author has observed a case of maniacal excitation slightly resembling acute delirium, slightly general paralysis, which died in three months without cerebal lesions, but with granulo-atropathic degeneration of the liver. He has also seen a delirium of chronic evolution without other lesion than a latent cancer of the liver. He compares these facts to the nervous manifestations of phosphorous poisoning, and concludes that insanity may follow when the liver does not suffice for the elaboration and the destruction of the organic substances.—*Archives gènèrales de Med.*,

Contributions to the Surgery of the Gall-bladder.*

Mermann gives a detailed report of operations on the gall-bladder done at the clinic at Heidelberg.

Five cases were Cholecystotomy; one a bloody dilatation of a pre-existing fistula; three ideal Cholecystotomies, three Cholecystenterostomies; two for extirpation of the gall-bladder. The indications for the surgical interference in these cases has been presented by Czerny in the (*Deutsch. Med. Wocha.* 1892, No. 23.

*Translated for The Medical and Surgical Reporter, by Marie B. Werner, M. D.

A Contribution to the Study of Fish Poisons.*

Drs. Fischel and Enoch have investigated this subject and arrived at the following conclusions. 1st. There exists among the fish a bacterial poison. 2nd. This in all probability originates from spore infection which gains entrance through abrasions or wounds. 3rd. The symptoms of this infection can be referred to the formation of a poison which has been propagated in the animal and is an albumose. 4th. This is identical with that of the bacteria Laprophytic formed from Toxalbumose. 5th. The infection can be found in some warm blooded animals and expresses itself by a paralysis of the respiratory and circulatory centers, also of paresis of the extremities. 6th. The infection can take place in the intestinal tract, after large ingestions of this poison. 7th. This poison is destroyed by boiling. 8th. By improper preparation of the fish as food this poison can be assimilated by the human being and produce the symptoms of poisoning.—*Fortschs. d. Med.* X. 8., 1892.

Auto-suggestion.—The Kitsune-tsuki.†

The kitsune-tsuki, or possession by foxes, is a curious mental affection observed in Japan and associated with internal hallucinations and a double personality. Foxes are the object of a superstitious belief on the part of a large proportion of the population, who attribute to them the power of assuming the human form; moreover, at times these animals choose the body of a living person as their dwelling place; the possessed then undergoes a veritable doubling of personality; he hears and understands all that the fox says and thinks, the latter speaking in a strange voice, quite different from the ordinary accent of the patient. This disease, according to Baret, appears to be a neuropathic delirium whose form is explained by the special superstitious ideas of the country. The treatment should be suggestive or rather exorcistic. The expulsion of the beast leaves the patient extremely prostrated, this prostration persisting one or two days, after which he frequently has lost all conciousness of the event.—*Jour. d'hyg.*, September, 1892.

ABSTRACTS.

OVARIAN DERMOID TUMORS.

Dr. J. Nigel Stark, reporting a case of "Ovarian Dermoid Tumor," says (*Edin. Med. Jour.*), concerning the development of such tumors.

Dermoids seem more liable to cause pain than other kinds of ovarian tumors. Probably the visible growth of most ovarian dermoids begins at puberty, when they participate in the development that then occurs in all the pelvic contents, and then by their slow, steady enlargement, they produce the distressing pressure symptoms,—rectal and vesical irritation, inflammatory attacks, dysmenorrhœa, etc.

As regards their frequency, Sir Spencer Wells says he met with 10 in his first 500 ovariotomies, and 12 in his second 500. J.B. Hunter states that they form between 3 and 4 per cent. of ovarian cysts. So far as I can judge the proportion is about 2 per cent.

Dermoids have been described as "cysts or tumors furnished with skin or mucous membrane (which may or may not be accompanied with the appendages peculiar to these structures), occurring in situations where skin and mucous membrane are not normally found." These appendages may be hair, teeth, bones, sweat-glands, sebaceous glands, etc. During the past few years much patient study has been bestowed upon dermoids; this cannot be wondered at, upon consideration of their peculiar structure and mode of formation. Doran, in his *Tumors of the Ovary, etc.* (1884), says we can only indulge in speculations regarding their origin, but that "the dermoid ovarian question appears to be closely and inseparably linked with some of the most profound mysteries of human life."

I shall mention very briefly only two of the earlier speculations as to their origin, as we have now reached some definite truths which enable us to form what is at least an exceedingly probable hypothesis. Elsner's theory was that they are all embryonal in their first structure, as they occur in places where the epiblast dips down to meet the hypoblast, and where by processes of grooved involution new bodies are formed, first in order being the testicle and ovary. Lawson Tait says that "the ovum has in it origin buds of certain tissues which, under exceptional hyperechetic action, may go on to the rudimental formation of these tissues without a fusion of the male germ." Bland Sutton, however, has brought forward a mass of evidence which demonstrates the fancifulness of such explanations, and proves the true explanation to be found in the identity of ovarian follicles with the acini of glands; or, putting it otherwise, in the fact that the follicles are mucous crypts. "Therefore, as the membrana granulosa is potentially mucous membrane, and as skin and mucous membrane are convertible structures and morphologically identical, cysts of the ovary containing skin or mucous membrane and their appendages are not more remarkable than cysts and neoplasms occuring in connection with other glands."

The study of the evidence which leads to these statements is of deep interest, and it is also so full of instruction that I shall now endeavor to gather it together in as concise a fashion as possible. And, in the first place, it is a universally accepted truth that skin and mucous membrane possess the same structural characters; it is also well known that the columnar cells of mucous membrane may undergo modification into the stratified cells of epithelium, as, to take a common example, in the case of hemorrhoids originally internal in situation, but which have become external to the bowel. In the study of comparative anatomy we learn that all the usual structures of epithelium—pigment, shell, hair, sebaceous glands, sweat glands—are also existent in the mucous membrane of various vertebrates. And, lastly, in this connection, the mucous membrane of the mouth, pharynx and conjunctiva has the same embryological derivation from the epiblast as has epidermis. Note also that dermoid cysts may contain mucous membrane and mucous glands as well as epithelium.

And now we have arrived at the point where the question as to the origin of ovarian cysts arises; but this confronts us with several difficulties, chiefly on account of the diversity of opinion given by dis-

tinguished observers who have made careful study of the subject. It appears to the ordinary reader an impossibility for him to form any definite conclusions. So far as my own reading and observation extend, I have a decided opinion that cysts of the ovary nearly always arise from changes in the follicles. In a case which I carefully examined, the follicles could be distinctly seen in every stage of degeneration, and Doran, Sutton, and others have narrated similar observations. That there may be other modes of origin is probable, but still the fact remains that most ovarian cysts arise from degenerative changes in the follicles. Taking this for granted, we now note that each follicle is lined by the membrano granulosa, which is composed of columnar epithelial cells, and secretes the liquor folliculi. Now, an ovarian follicle passing through the various stages to become a multilocular cyst may retain the simple lining of epithelium upon the loculi, or else the epithelium may undergo growth; diverticula are sent off, and in this manner the immense number of cysts formed. The cells lining these cysts are different in appearance to those of the membrana granulosa, but, as we have seen, it is admitted that epithelium does change its character according to circumstances, and is also readily convertible into mucous membrane. So far the case is pretty evident and capable of proof, but now, as Sutton says, "the mystery up to the present time has been to definitely account for the origin of glandular tissue in such cysts, for it is well established that adenomata can only arise in connexion with pre-existing glandular tissue." He then goes on to say that as the membrana granulosa secretes the liquor folliculi, it therefore possesses the functions of a glandular structure, and that we must compare ovarian follicles and glands in general, "in order to ascertain if any phylogenetic justification exist for their extraordinary behavior." The latest investigations upon the development of ova and ovarian follicles show that the cells, which Foulis and others proved to be germ epithelial, and from which the ova and follicles are derived, are of the same nature as those cells which in the bowel form the mucous glands. From a developmental point of view there is, therefore, evidence of the identity of the ovary with a secreting gland, and on morphological grounds this can also be proved. For example, the ovary of the frog in the breeding season consists of a main cavity with numerous diverticula which are lined with cells. Some of these cells are larger than the others and are really ova. In mammals the more complicated structure with which we are familiar replaces the simple gland as seen in the frog, but essentially it is the same, the acini of the gland becoming represented by the follicles. Looking at this question from a pathological standpoint, we find the most intimate connection between the diseases which attack ovarian follicles and those sometimes existing in the acini of other glands, such as the mammæ. Thus, link by link, the chain of evidence has been formed which leads to belief in the opinion that ovarian follicles are identical with the acini of glands, or, otherwise, are mucous crypts, and, as we have already proved and stated, the membrana granulosa is potentially mucous membrane, and therefore identical with skin, so that, as we previously said, cysts containing skin or mucous membrane and their appendages are not more remarkable than cysts and neoplasms occurring in connection with other glands."

VIBRATORY MEDICATION.

Prot. J. M. Charcot, of Paris, (*International Medical Magazine*) speaking of the application of rapid and continuous vibrations to the treatment of some diseases of the nervous system, states:

"At first the effect of mechanical vibration was tried on patients who had hysteria. A very large tuning fork was mounted on a sounding box and set in motion by a bow. This system gave Dr. Vigoroux good results in hemianæsthsia, and caused a certain class of contractions to relax. In a case of locomotor ataxia he succeeded in relieving the pains by placing his patient's legs in the sounding box. In fact, a number of experiments, repeated at different times, showed that the vibrations of a large tuning fork have exactly the same

physiological action as magnetic and static electricity. For many years I have learned from patients who were attacked by paralysis agitans, or Parkinson's disease, that they felt much better after long trips by rail or by carriage. During these journeys they get rid of those painful sensations they had at home, and this improvement persisted for some time afterwards. Therefore I have constantly told my students that it was possible that some good could be obtained in Parkinson's disease by movements similar to those of a moving wagon or a train.

With this idea in view Dr. Jegu (Dr. Charcot's Assistant) aided by M. Solignac an engineer, made an arm-chair having a special mechanism which causes it to oscillate rapidly on both its anterior and lateral axes. These combined and varied movements produce a trepidation or trembling that is similar to that felt in a running wagon. Dr. Jegu made a number of trials with his chair, but dying shortly afterwards, Dr. Gilles de la Tourette, a former *chef de clinique* of Dr. Charcot, took up these experiments, and up to the present has tried them in eight cases,—six men and two women. Without making any attempt to analyze the very satisfactory results obtained, we will describe them: An amelioration takes place after the fifth or sixth sitting: The method is mostly of use for the painful sensations in paralysis agitans. As soon as the patient gets off the "trembling arm-chair" he feels lighter and the stiffness is gone. He can walk much better, and he is able to sleep at night. This last is the most important improvement. Except in one case the trembling of the patient was not changed. This improved state is always felt the day of the treatment, so that it should be repeated every day. The results are important in this malady where we have so far, not been able to find anything to give relief.

Dr. Gilles has had an apparatus constructed which is designed to give intense vibrations to the cranium. This apparatus is a sort of helmet with separated blades, that looks like the "conformator" used by hatters to get the shape of the head for hats. By a simple device this helmet fits any head. It has a plate on top on which is placed a small electric motor, moved with an ordinary battery. This motor gives six hundred revolutions per minute, works easily and regularly and produces an uniform vibration which is transmitted to the cranium. The whole head vibrates under it. When the apparatus is in motion you hear a soft humming noise which should be taken into account in studying the results obtained. The number and extent of the vibrations can be regulated. This "vibrating helmet," put on the head of a healthy subject, is well tolerated and does not cause any annoyance. In seven or eight minutes a sensation of numbness is experienced all over the body and the person becomes sleepy. Given for ten minutes at six P. M., a night of calm sleep will follow. Eight or ten sittings cure insomnia when not associated with any organic brain disease. In three cases it was found very efficacious in sick headache (migraine.) Three persons having neurasthenia were treated; two were cured, while the third did not continue the treatment, although improved. This form of vibration acts in neurasthenia by taking away, first, the cephalic symptoms,—vertigo, and the painful frontal constriction which is so characteristic of this affection. What seems to show that these vibrations have a particular action on the brain, is that in one case where the spinal symptoms were predominant, the usual weakness of the inferior members and the sexual impotence disappeared without having to make any vibrations down the spinal column. Static electricity had failed in this patient.

It cannot, therefore, be any longer doubtful that vibrations of this nature are a powerful sedative to the nervous system. No definite data are at present offered as a number of experiments are to be made, but the present statement is made merely to show the possibilities opened up by vibratory medication.

The largest private medical library in the country is said to be that of Dr. Senn. It contains about 20,000 volumes.—*Ex.*

Doctor—Ben, what's your face so bunged up for?

Ben (sadly)—Dat fool George Williams done it; I was at de cake walk las' night, and all I say to his gal was, "good ebnin, Miss Annie, you's lookin' quite pregnant dis ebnin." What make him hit me, doctor?

HYDATIDS OF THE BRAIN.

Dr. Herbert Barclay (*the New Zealand Medical Journal*) in speaking of "Hydatids of the Brain" presents a case with the following history: A young man aged 20, small and stunted in growth, though otherwise active and healthy, "was constantly among sheep and dogs." When seen for the first time, August 7, he complained of a headache; his tongue was slightly furred, pulse about 70, pupils equal and reacted to light. After a few doses of the bromide, and 5 grains of calomel, all symptoms disappeared. On August 13, he was in good health and spirits, but that night he vomited, which he attributed to excessive smoking. On the evening of the 14th, complaining of a severe headache, he passed into a dazed condition and died.

His relatives relate that he sometimes said "his head felt as if too full of blood, and wished that his nose would bleed." Except of the vomiting, already mentioned he did not, at any time, complain. But for a day or two before he died he had noticed a dimness of vision. He had no convulsions. After complaining very much of the headache he became stupid, passed into a state of coma, with stertorous breathing, which gradually deepened till his death.

At the *post mortem* the following conditions were noted: On opening the skull, the dura mater was hyperaemic and the superficial cerebral veins were much distended. On the under surface of the brain was a cystic growth about the size of a pigeon's egg and extending into the brain tissue for at least half an inch. The growth extended from the anterior aspect of the pons varolii to the optic commissure in front. It was composed of one or two cysts, containing clear or brownish fluid; in one part the growth was translucent and in another red and opaque. The anterior part of the swelling contained a few hard particles, apparently chalky concretions. The tumor was quite extra-cerebral, and careful dissection succeeded in turning it completely out of its bed without disturbing the brain tissue. The brain, infundibulum and copora albicanti—the parts pressed on by the upward growth of the cyst—were almost entirely obliterated.

This case is interesting for several reasons. It emphasizes a fact already noted (Graham on "Hydatid Disease") that symptoms, except headache, may be entirely absent. The absence of such symptoms as hemiplegia, vomiting and convulsions were no doubt due to the situation of the growth; and the absence of visual defects was due to the direction in which the growth was expanding. The immediate cause of death was compression of the brain from the stoppage of the circulation, and the giddiness, vomiting and gradual loss of eyesight were no doubt due to the same causes; in fact, the condition simulated apoplexy, and no doubt had the same symptoms occurred in a man of 60 or 70, a death certificate would have been forthcoming.

The impediment to the venous blood flow by pressnre on the sinuses caused the distension of the vessels on the brain surface. The paroxysmal nature of the headache was evidently due to the over-pressure, and as this was relieved by 5 grs. of calomel or by a purge, the rapid cure affected is readily accounted for. The headache would not return till a gradually increasing or varying distension became uncomfortable. The boy himself, before he died, complained of feeling his head too full of blood, and there is little donbt that venesection done early enough would probaly have warded off the fatal issue. Graham says tbat blindness is generally a marked symptom wherever the growth is situated, but in this instance—though attached to the optic tracts—it was never a symptom till the case was becoming fatal, and was due, just as likely, to pressure on and abolition of the function of the occipital lobes as to any local pressure on the commissure or tracts.

The surrounding brain tissue was not found condensed, the usual condition when hydatids attack other organs, though it is occasionally absent. The attempted cure by calcification of the cyst is also interesting, and it seems possible that it might have ended in complete recovery. Dr. Roberts, of Dunedin, the pathological lecturer in the University, examined the growth and considered it an inspissated hydatid tumor.

"This machine only registers 250 pounds, and I weigh in the neighborhood of 300."

"Oh, well, if you want to ascertain your exact weight, drop a nickel in twice, and foot up the aggregate."

THE TREATMENT OF DIABETES MELLITUS BY MEANS OF PANCREATIC JUICE.

In the *British Medical Journal* for January 7th, Dr. Mansell-Jones suggests that as the juice of the thyroid gland appears to be almost a specific in myxœdema, pancreatic juice administered before or after meals should be given a fair trial in diabetes, as this disease, he adds, in most cases, appears to be due to disease or disordered function of the pancreas.

Neither pathology nor physiology, however, lend much encouragement to the hope that diabetes mellitus will prove tractable in such a simple way. In the first place, the pathogensis of this disease is much more complex than that of myxœdema, and diseases of the pancreas account for probably only a fraction of the cases of this malady. In the second place, even if it were a fact, that in most cases diabetes was due to disease or disorder of the pancreas, the analogy of this doubly-active gland both excreting and secreting, with the ductless thyroid gland is not a very close one. There is some reason, however, on theoretical grounds, for the belief that pancreatic juice might have some beneficial effect even in non-pancreatic diabetes.

The recent researches into the pathology of the pancreatic form of diabetes mellitus, of which a most interesting account was given by Dr. Vaughan Harley, (*Br. Med. Jour.* Aug. 27th, 1892,) makes it very probable that, in addition to the well-known tryptic, diostat-splitting and milk-curdling ferments, a glycolytic ferment is also produced by the pancreas. Assuming the existence in the normal pancreas of this latter ferment, I thought it possible that the administration of a pancreatic extract by the mouth might have some beneficial action in diabetes mellitus by assisting to destroy the sugar in the blood. Acting on this idea, therefore, I anticipated Dr. Mansell-Jones's suggestion, and for some time past have been treating in a tentative way two pronounced cases of diabetes mellitus under my care at the Royal Free Hospital, by the administration of a liquor pancreaticus in half-ounce doses given three times a day immediately after food. It is the generally received opinion that when given in this way, the liquor has no appreciable digestive power, so that we may put the latter effect on one side. No other medicine was given after this treatment was started, and in every respect the patients remained under the same condition as before.

In both cases the patients have assured me they have experienced benefit from the treatment. I should not have attached so much importance to their statements had it not been that without any suggestion on my part or collusion on the part of the patients, who attended on different days, there was a remarkable agreement in the accounts they gave of this beneficial effect. They both said they had lost to a great extent their feeling of lassitude and languor, and felt stronger in every way. Their thirst, moreover, had considerably lessened, and they had passed a smaller quantity of urine. These beneficial effects moreover, have continued. The specific gravity of the urine and the relative amount of sugar have, on the other hand, not been affected.

In an in-patient under the care of my colleague, Dr. Samuel West, his house-physician, Dr. Rendel, informs me that since the administration of liquor pancreaticus, the amount of fluid imbibed during the twenty-four hours, which had previously averaged 12 pints, has fallen to 6 pints, with a similar decrease in the amount of urine passed.

In a disease like diabetes we must be thankful for even small mercies. For myself I would rather find an improvement in the general condition of the patient, increased strength, diminished thirst, diminished quantity of urine as a result of treatment than a mere diminution of the amount of sugar in the urine without such improvement. I should have preferred of course, to have found both results. It is evident that liquor pancreaticus is no specific, but the effects in these cases are encouraging enough to induce me to make further trial of it, and it is possible that in cases of true pancreatic diabetes the benefit might be greater.—*Br. Med. Jour.* Jan. 14th, 1893.

Thermometric Observation.

"Mamma," said little Johnny, "if I swallowed a thermometer would I die by degrees."—*Exchange.*

THE LIBRARY TABLE.

Traite de Medecine. Charcot.—Bouchard et Brissand. Tome III. Paris, G. Masson. 1892.

In this, the third volume of the "Traite," the excellent standard set up by the two previous ones is well kept up. The point of view of the modern clinician with his views of bacteriological infection and his antiseptic prophylaxis and therapeusis is every where taken. Even those conservatives who remain true to less radical views will find the acute and dispassionate discussion of such subjects as diphtheria and croup, their relations and differences, an excellent example of scientific presentation of the facts. The author (Ruault) contends for the view, long held in France, of the identity of diphtheria and croup, contrary to the opinions of Virchow, Rokitansky and other German pathologists, who, basing their views upon the pathological anatomy of the two affections, regarded the one as infectious disease of a gangrenous nature and the other as a simply inflammatory condition.

As to treatment M. Ruault believes in local therapeutics, and seems to think it necessary to fight valiantly for this almost unanimously held opinion. In speaking of the prophylaxis, a matter of special interest to us at this moment in view of this winter's epidemic, no suggestion is made of any such ridiculous plan as the absurd house quarantine of our ingenious Board of Health. Directions for the protection by a special covering, such as some sort of smock frock, of the clothes of these in contact with patient, for the disinfection of all articles in use by boiling water or great heat, and for the cleansing of the hands by a solution of carbolic acid, which Chautemesse and Widal had found the most effective against the baccillus of Klebs. As an alternative to carbolic acid he recommends the acid sulphoricinate of soda, a substance of which little is known in this country.

No word is said of the present favorite peroxide of hydrogen, although in all other respects the article is well up to its date of March, 1892. This practice of dating articles pursued throughout the work is, by the way, one much to be commended.

Other subjects treated, and mostly well treated in this volume, are diseases of the stomach, pancreas, intestines, liver and peritoneum. The latter seems to us the least adequate, especially in its too scant mention of the surgical handling of appendicitis.

Clinique des Maladies du Systeme Nerveux. M. le Professeur Charcot. Paris, 1892. Tome I.

This volume contains a collection of the lectures of Prof. Charcot, and of papers published from his service during the years 1889–91, by his various chiefs of clinic and hospital internes.

They are mostly on the more recently described or differentiated forms of nervous diseases, but are rather suggestive, as clinical lectures should be, than exhaustive. It is a pity that the desire of print should have become so strong as to cause the publication of papers so little complete as some of these. In the place of the careful, accurate and thoughtful work which Charcot's name would once have guaranteed, we have a series of superficial studies of small importance. The most interesting we have found are those on hystero-traumatism, on hysterical œdema, on ophthalmoplegic migraine and the remarks in the lesson on a case of male hysteria upon the frequency of occurrence of hysterical troubles in that sex, a frequency much greater in Europe than in this country. Charcot thinks hysteria major, "la grande hysterie," perhaps even more common among men in the lower classes than among women, though slight hysterical manifestations affect women more than men. The case reported had complete lateral facial anæsthesia with paralysis of the buccinator and greater zygomatics muscles only; he had hysterical convulsions with opisthotonos, a hysterogenetic area in the left hypochondrium and symmetrical narrowing of the visual fields—certainly a sufficiently curious case.

CURRENT LITERATURE REVIEWED.

INTERNATIONAL MEDICAL MAGAZINE.

The January issue of the *International Medical Magazine* offers eight papers as "Original Communications." Five of these were read before the American Climatological Association last June.

Drs. Curtin and Watson, in an article entitled

The action of Influenza Poison on the Heart, and a Study of Influenzal Angina Pectoris,

consider that all treatment lies in finding out the cause of the peculiar condition of the heart during and following influenza, and as as a basis for this inquiry the condition of the heart itself. That the heart condition is evidently not due to anæmia and a consequent weakened condition of the heart wall, is shown by the rapid onset of symptoms and their frequent rapid subsidence. It is not inflammatory, for inflammations of the endocardium are exceeding rare, and all endocardial trouble was not prone, during the epidemic, to be aggravated or lighted up afresh, and subnormal temperature generally existed. Even articular rheumatism associated with influenza had little tendency to exo- or endo-cardial mischief. In some protracted

cases the long-delayed fatal event may have been due to nutritional changes in the heart muscle, consequent to continued faulty innervation.

Under treatment arsenic is recommended as valuable in anæmic cases, and one-drop doses of Fowler's solution before feeding seemed to increase retentive and digestive power. Bromide of ammonium quieted restlessness; sulphonal generally had a good effect, was occasionally dreaded by the patient, but generally was the most satisfactory hypnotic, often combined with bromides. Paraldehyde, when well borne, was useful.

The prognosis was hopeful in almost every case no matter how desperate it seemed, except in the aged with organic heart disease, cardiac degeneration and senile weakness. Recovery was the invariable rule in the young and robust.

Treatment ot the anginal cases differed but little from that employed for weak hearts from other causes. Excessive and over-stimulation of the nerves was to be ever guarded against, for it sometimes aggravated the symptoms. The quieting effect of rest in bed, with the attending protection from cold, fatigue and draughts, was of the greatest importance in treating the anginose cases.

"A case of extreme prostration following an attack of influenza; repeated threatened heart-failure; peculiar cardiac irregularity; Recovery" is presented by Dr. Platt.

Dr. Robinson's paper

The value of Conservatism in the treatment of some common Nasal and Throat Diseases especially among Children

is a plea to the general practitioner to refer to the specialist those cases of nasal and throat diseases that are so little understood by the average practitioner. He takes, as an example, a small child from infancy up to four or five years of age, who has the "snuffles" with decidedly obstructed breathing. He says "the family physician contents himself with prescribing some aconite or nitre or perhaps a hot foot-bath," whilst the specialist under these conditions, uses one or more applications, at suitable intervals, of glacial acetic acid, or of mono-chloracetic acid, by means of a flattened probe wrapped with cotton, which will relieve the child's breathing sufficiently to render further or different interference quite unnecessary. The doctor takes for granted that the general practitioner's knowledge in these cases, is limited to the use of internal medication alone.

Dr. Quimby has quite a lengthy paper on "The Pneumatic Cabinet in the Treatment of Pulmonary Phthisis."

Prof. Charcot has a paper on "Vibratory Medication; the Application of Rapid and Continuous Vibrations to the Treatment Diseases of some of the Nervous System," fuller mention of which is made elsewhere.

THE NEW ZEALAND MEDICAL JOURNAL.

The quarterly issue for October comes to us with twelve carefully prepared articles. We notice elsewhere the paper of Dr. Barclay, "Hydatids of the Brain."

Dr. Barnett reports a case of "Malignant Endocarditis."

Dr. De Lantour has a

Case of Twins—Locked Heads

to offer. The patient was a primipara, aged 22. After the diagnosis was made and verified by Dr. Wait, who did the operating, the first child was decapitated and the body delivered. As the "patient seemed to be suffering from shock and getting weak," a craniotomy was performed on the second child and it was quickly delivered. Then came the difficulty of extracting the loose head which had been pushed back to permit the other head to come down. After some difficulty it was secured by a crotchet and delivered. The patient made an excellent recovery without a bad symptom, and has had two ordinary pregnancies since.

The writer has a second paper in this number, of interest from the fact of its infrequency.

A Case of Complete Spontaneous Inversion of the Uterus

following birth. The doctor was in the act of delivering the placenta, his left hand firmly over the uterus, holding the umbilical cord loosely in his right hand, and feeling the uterus contracting, said, "Bear down, and give a little cough" She did bear down and gave a tremendous cough. The abdominal tumor disappeared and a large mass shot out on to the bed extending down almost to the knees. This on close inspection proved to be not only the placenta, but the uterus, fallopian tubes and ligaments. The placenta was quickly peeled off, the fundus and body of the uterus was bathed with a warm bichloride of mercury solution—1 to 1000. Treating it like a hernia, gradually applying pressure and reduction, the whole mass returned. There was no hemorrhage or shock; gave brandy, ergotinine and opium; kept her in bed for four weeks. Attended same patient in second pregnancy which was quite natural; she recovered without a bad symptom, and got up on the fourteenth day.

Dr. Thomas has a paper on

Constipation

which he considers under the two heads of *local* and *general* causes. The *local* causes comprise all those conditions which so act, from without or within the large bowel and rectum, as to impede the onward movement of feces through these parts, either by narrowing some portion of the canal or by interfering with its functions, e. g., the pressure and irritation of scybala; putrefactive gas, worms, concretions and tumors of various kinds, a weakened condition of the expiratory abdominal muscles as seen in repeated pregnancies, and especially after twins, obesity, inflammation, lead-poisoning and painful affections of abdominal walls, diaphragm or pelvic viscera. The *general* causes are referred to under the heads of *temperament*, *habits* and *errors in diet* and *dress*.

Dr. Irving presents an article on "Postpartum Hemorrhage."

NEW YORK JOURNAL OF GYNECOLOGY AND OBSTETRICS.

The January number of this journal contains five papers, two of these—Dr. Potter's "Specialism in Medicine, particularly as related to Surgery and Gynecology," and Dr, Kollock's "Craniotomy on the Living Fœtus is not Justifiable" appeared in THE MEDICAL AND SURGICAL REPORTER Dec. 3, 1892, as part of the transactions of the Southern Surgical and Gynecological Association. Dr. Ingraham reports three cases of "Ectopic Pregnancy" with the usual history of such cases. "The Prevention of Hernia after Incision of the Abdominal Walls," is the subject of a paper by Dr. Edebohls.

THE OPHTHALMIC REVIEW

For November contains an original paper by Archibald S. Percival on "The relation of Convergence to Accommodation and its Practical Bearing." Amongst the reviews is one of especial interest:—Galezowski on

Changes in the Ciliary Circle and the Examination of this region in Constitutional Affections and in Myopia.

The Ciliary Circle, which consists of the anterior portion of the retina, the ora serrata and the ciliary body, is a region of the eye which has not, in the author's opinion, received sufficient attention from ophthalmoscopic observers. This neglect has arisen from the difficulty of getting a proper view of the region. For the purpose of making the examination of the ciliary circle as easy and complete as possible, Dr. Galezowski has had a lens of short focus joined to a very strong prism, which combination he uses, presumably, with the ophthalmoscope. He states that the association of opacity of the anterior part of the vitreous with changes in the ciliary circle is so constant, that in making statistics of the former, the author found ophthalmoscopic evidence of changes in the ciliary region in 98 per cent. In choroiditis of syphilitic origin there is a constant presence of atrophic patches at different points of the ora serrata. Tnberculous lesions of the ciliary circle are recognized as small grey-white elevations, with surrounding serous infiltrations and with pigmentary deposits here and there. Gouty effusions are seen in the form of sanguineous effusions into the choroid or vitreous.

THE BRISTOL MEDICO-CHIRURGICAL JOURNAL.

For December contains four articles. Dr. Skerritt, the President of the Bristol Society chose as the subject for his annual address,

The Teachings of Failure.

In looking back upon the medical history of the past, two episodes stand out in bold relief before him—one, the history of tuberculin; the other, the onslaught of influenza. The former is a thing of the past; the latter he trusts, is so too, and upon neither can we, as a scientific, profession, look with satisfaction. Koch led us away after a will-o'-the wisp; the Influenza did with us what it would; and the contemplation of this has turned our thoughts towards an aspect of work upon which it is good for our mental discipline that we should at times meditate.

Drs. Davy and Blonfield present "Two Cases of Locomotor Ataxy with Charcot's Joint disease." They point out in presenting these cases what M. Charcot has long ago called attention to, that the arthropathy is an *early symptom* in locomotor ataxy, and that the absence of pain and inflammation is a most important point in the diagnosis of all diseases of the joint caused by locomotor ataxy.

"Health Resorts in the West of England and South Wales" are presented by Dr. Brabazon. Dr. Prichard has quite a lengthy address on "The early history of the Bristol Medical School," which was delivered at the formal opening of a new wing of the University College.

HARPER'S MAGAZINE.

The first article in the February *Harper's* is an exposition of Shakespere's "Twelfth Night." The illustrations by Edwin Abbey are seconded with "comment" by Andrew Lang. The pictures are inimitable. The poet Whittier is written of, and his haunts are beautifully illustrated. Julian Ralph writes critically and entertainingly of New Orleans, which he calls "Our Southern Capital." His eyes see much that is new, and Smedly, the artist, helps the reader to understand Mr. Ralph's descriptions. The most interesting thing in this magazine is the powerful and absorbingly interestlng serial, "The Refugees." Several short sketches, the usual poetical efforts and the editorial departments make up the balance of the magazine. It is a good number.

THE MEDICAL CHRONICLE

of Manchester, England, for January contains a paper by Dr. Thomas Barlow on the

Prognosis of Chronic Alcoholism in the Light of its Pathology.

The author compares the effect of alcohol taken continuously in the system to that produced by other poisons, such as lead, mercury, arsenic, etc. The treatment advocated is the absolute withdrawal of the poison and the substitution of good food. The idea that delirium tremens will follow the cessation of the daily dose of alcohol is discussed, the author's opinion being that it does not ensue. The outlines of chronic alcoholism are well presented.

Dr. E. Stanhope Bishop contributes a paper on

Faradism in Cases of Slight Prolapsus and Retroflexio Uteri.

After reviewing the advantages of and objections to Alexander's operation for the relief of this condition, the author reports a number of cases in which he used faradism with good results. One electrode was placed in the vagina, pressing against the os uteri, whilst the other was applied for a third of

the seance to each great sacro-sciatic notch and the back immediately above each posterior superior iliac spine; then for one-third each to the inguinal canals and external abdominal rings. He has treated thirty-two cases in this way. Twenty-five of these have been satisfactory; five have failed; two are still under treatment.

The other papers in this number are: "Observations on General Pathology of Cancer—Particularly Cancer of the Breast," by Dr. W. Roger Williams. The report of a case of "Silent Pneumonia," where there were neither breath sounds not adventitious sounds over the lower lobe of left lung, by Dr. Graham Steele. Dr. D. Lloyd Roberts reports "Cases of Ovarian Cystic Tumor," and Dr. T. N. Kelynack a case of "Acute Perforative Appendicitis."

KANSAS MEDICAL JOURNAL.

"Belladonna, with some of its Therapeusis," is the title of a paper by Dr. J. E. Minney. The various indications for the internal use of Belladonna, as well as its use in eye surgery, are discussed. The paper contains nothing new.

Dr. H. L. McIlhenny contributes an article on

Pelvic Presentations and their Management.

While the article is but a reiteration of the well known rules governing these cases it is well worth reading, as the author speaks from his own experience which has been a rich one. He thinks that the troublesome condition where the arms go up over the head in the pelvis is not of necessity caused by traction on the body, as he states that it has occurred where no traction has been made. Forceps, he thinks, should not be applied to the after-coming head unless there is a disproportion between the head and the pelvis.

The other articles are "Chronic Tubular Nephritis" by Dr. R. E. McVey, and the report of a case of "Laryngitis," where tracheotomy became necessaay owing to œdema of the larynx, by Dr. S. C. Pigman.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY

for January contains, besides the proceedings of the Obstetrical Society of Philadelphia, which have already been given in the columns of this journal, the

"Report of a case of Gastrotomy or Laparotomy,"

by Dr. R. E. Haughton. The birth of the patient's second child was followed by acute terminating in chronic suppurative peritonitis. At the operation a large suppurating cavity was found between the peritoneum and the abdominal walls which was incised and drained. The peritoneal cavity was not opened. Later, a fæcal fistula developed, communicating with the abscess cavity. This healed spontaneously.

Under Society Proceedings there is a paper by Dr. W. W. Potter on "Posture in Relation to Obstetrics and Gynecology," with photographs of models taken in the various postures—horizontal, genu-pectoral, Trendelenberg, etc. That any journal, even that of a specialty, would admit this paper suggests either a lack of self-respect, a poverty of resource, or a veiled advertising arrangement. The aggregation of words affords an inefficient setting for the obscene photographs displayed, and the excuse offered for the exhibition of nudity is an insult to the intelligence of the profession.

PERISCOPE.

MEDICINE.

Dr. J. T. Carpenter, Jr., (*Philada. Polyclinic*) calling attention to severe burns of the conjunctiva by the instillation of calomel while giving potassium iodide internally, in course of his remarks states that the cases that came under his notice showed that although no permanent damage was done, the inflammatory reaction was severe and caused a muco-purulent conjunctivitis, accompanied by chemosis and œdema of the lids with great suffering.

The iodide is excreted by means of the tears and when calomel is instilled into the conjunctival sac, biniodide of mercury is formed which is a severe caustic. It is in a large clinical service that this mistake is most likely to occur, where, owing to the number of cases and the short time in which to treat them, inquiries as to what medicine is being taken are apt to be neglected, but it may occur in one's private practice. Certain it is, that the caution is a practical one; *do not use calomel where iodine or iodides are being administered.*

SURGERY.

Relation of Albuminuria to Surgical Operations.

In a paper upon this important theme, read before the Southern Surgical and Gynecological Association (*Virginia Medical Monthly*, December, 1891), Dr. Long arrived at the following conclusions:

1. Ether or chloroform rarely injures healthy kidneys.

2. When renal disturbances occur from the use of an anæsthetic, the kidneys being healthy, they are due rather to prolonged narcosis, exposure of the patient, or perhaps to the combined influence of the operation and the anæsthetic.

3. A mild degree of albuminuria (or nephritis), especially if recent, is not a contraindication of the use of chloroform.

4. Even in the presence of advanced and extensive renal changes, an anæsthetic may be employed, provided the patient or the family be advised of the additional risk.

5. Of the two anæsthetics usually employed

it is yet a mooted question as to which is the safer, so far as the kidneys are concerned, unless it be in obstetrical operations.

6. While it is by no means the rule, profound functional disturbance, and even organic lesions may be induced by an operation, apart from the influence of the anæsthetic.

7. Such renal changes are due to reflex sympathetic action, or to sepsis, or both.

8. Operations in certain regions—notably, the abdominal genito-urinary, anal, or rectal, are especially liable to produce renal complications.

9. A healthy condition of the kidney *minimizes*, but does not obviate the danger referred to.

10. Albuminuria is always an indication of renal lesions, and should be regarded with distrust, but is not a positive contraindication to an operation.

11. When albuminuria is associated with other evidences of advanced renal changes, no operation should be undertaken without candidly stating to the patient or friends the dangers incident to the condition of the kidneys.

12. Paradoxical as it may seem, an operation will sometimes relieve an albuminuria due to acute affections.

13. No surgeon is justified in undertaking an operation without first knowing the state of the patient's kidneys.

Phimosis and Circumcision.

My observation, experience and mature deliberation have led me to conclude in this matter:

1. That each male child should be examined at birth for obstructive phimosis when we examine for imperforate anus.

2. That the prepuce should be retracted fully, and all adhesions to the glans broken up, all smegma be removed, and the nurse be instructed to retract, wash and anoint the parts daily for two weeks and once each week thereafter.

3. That a long and redundant foreskin, though freely retractable, may be a cause for local and reflex diseases, may occasion, or at least exaggerate, an undue sexual appetite, and so predispose to masturbation, sexual excesses, and ultimately to venereal diseases.

4. That such cases should be circumcised, as should the cases where the foreskin is not retractable.

5. That routine circumcision of all male infants is to be condemned. That the prepuce plays an important part in the human economy, and should not be amputated except for good and sufficient reasons.

6. The unhappy experience of the fatal case cited, demonstrates that this little operation may be attended by grave dangers, and should be undertaken with this risk in view, and only after we are assured that the parents' families are not bleeders.

7. That infants may endure a copious hemorrhage far better than we have heretofore supposed.—*Dr. Wetherill, Univ. Med. Mag.*

Laryngeal Intubation.

Max Scheier gives (*Arch. de Laryng.*, etc., November-December, 1892) the experience of intubation in the Urban Municipal Hospital in Berlin, during what is described as an exceptionally severe epidemic of diphtheria. The operation was performed in 16 cases of acute diphtheria with three recoveries. Of the 13 who died all were submitted, subsequently to the intubation, to tracheotomy, with the exception of one, a child, aged 4, in whom the tube was retained for two days and a half, death being due to cardiac paralysis. The results of subsequent tracheotomy were thus very unfortunate; only one, a case enumerated among the recoveries after intubation survived. Before introducing the tube, the mouth, the tonsils, and the uvula were swabbed with an antiseptic solution, and all membrane thus loosened removed. The solution used for this purpose was either a 1 per mille solution of thymol, or the following: Salicylic acid 3 parts, boric acid 30 parts, distilled water 1,000 parts. Among the causes of failure of the operation Scheier enumerates swelling of the epiglottis and ary-epiglottic folds, and he reccommends that a laryngoscopic examination should, if possible, be made before attempting to introduce the tube. Another cause of immediate failure is pushing membrane in front of the tube into the trachea; in some of the cases of apparent failure the tube when removed brings away false membrane or a plug of mucous, and breathing is then improved. A nurse must be kept in constant charge of the case after intubation with instructions to remove the tube by pulling on the string if the dyspnœa become severe; this withdrawal is in most cases immediately followed by some relief to the dyspnœa, which may endure for several hours. Expulsion of the tube by cough was observed only in cases in which the intubation was done for acute diphtheria, and was due to the tube becoming plugged with mucous. Scheier does not think that the accident was due to the use of too small a size. He is inclined to think that the difficulty in deglutition has been, at least, exaggerated. As a rule, he found there was none after the first two or three attempts; when more persistent he believes it to be due to the inflammation itself and not to the tube. In the treatment of stenosis after tracheotomy intubation was very successful, whether this stenosis was due to a spur or to the formation of granulations. Such granulations may have formed at the upper or lower border of the tracheal wound by the time it is proposed to withdraw the tracheotomy tube, or they may develop much later at the site of the tracheal wound. Scheier believes that intubation will also be valuable in diphtheria of the wound and skin after tracheotomy; it was also instrumental in saving life in a case of severe secondary hemorrhage after tracheotomy. His conclusion is that intubation will prove to be a valuable auxiliary in the treatment of laryngeal stenosis due to diphtheria, but that its most important field will be in the treatment of chronic stenosis of the larynx.—*Ex.*

The Use of Cocaine.

1. Amount of cocaine used must be in proportion to extent of surface it is desired to anæsthetize. In no case should the quantity exceed one grain and three-quarters.

2. Cocaine should never be used in cases of heart disease, pulmonary disease, or in persons of highly nervous temperament.

3. In injecting cocaine, the intradermic method is preferable to hypodermic. By injecting into, not under mucous membrane or skin, the risk of entering a blood vessel is avoided.

4. During injection patient should always be in recumbent position; in operations upon the nose and throat the head should not be raised until anæsthesia is complete.

5. It is of great importance that cocaine should be pure, since its combinations with certain other alkalies result in poisonous compounds.—*Brooklyn Medical Journal.*

Deaths Under Chloroform.

The stream of deaths from chloroform during inhalation still flows on in undiminished volume, and while much is said and written about the methods of restoring collapsed patients. there is little about how to prevent collapse. It has not yet come home to doctors generally that the want of oxygen is the direct cause of the collapse, but we notice a practical suggestion of Dr. G. H. Nicholson, of Liverpool, which may lead to some good. He advises a combination of oxygen with the chloroform-vapour, and says that this keeps up the blood-pressure and maintains respiration in a way that gives confidence to the operator. This is well worth trying.—*The Chem. and Druggist.*

OBSTETRICS.

Spontaneous Cure of Rupture of the Uterus.

Richter (*Deut. Med. Woch.*, November 1892) was called to a case in which during labor the pains had ceased, the presenting part had retreated, and the patient had suddenly become faint and had vomited. Abdominal palpation discovered a foot apparently immediately beneath the abdominal wall. The author then seized the other foot, turned, and delivered, there being much difficulty in getting the head through the contracted pelvis. The child was born in a condition of asphyxia; it was "Schultze'd" for some time, but without result. The placenta had to be removed manually, when a rent was found to the front and left of the uterus, through which three fingers could be passed immediately beneath the abdominal wall. No douching was practised. A sandbag weighing two pounds was placed on the abdomen, and several doses of ergot given. The patient recovered. In all the manipulations every antiseptic precaution was taken. The case shows that even rupture of the uterus may heal spontaneously if septic infection be avoided. The slightness of the bleeding from the rent was due, in the author's opinion, to the infant's leg acting as a tampon.—*Brit. Med. Jour.*

Treatment of Post-Partum Hemorrhage.

Tarnier (*Journ. des Sages Femmes*, December 16th, 1892) strongly insists on the recognized modern treatment, namely, clearing out clots by the introduction of the hand into the uterine cavity, followed by hot water injections. At the same time he advises that a small dose of alcohol be given. Should these means fail, ergot must be administered; 7 or 8 minims of the aqueous solution of ergotinine, hypodermically, act best. If the flooding still goes on he advises, before resorting to the extremity of plugging the uterus, that an intrauterine injection of the following solution be given pure:—Tincture of iodine 30 parts, iodide of potassium 10 parts, distilled water 60 parts.

GYNECOLOGY.

Vulvitis with "Gonorrhœal Rheumatism" in a Child aged 2.

Lop (*Gaz. des Hop.*, No. 42, 1892) relates a case of mono-articular arthritis following vulvitis in a girl aged 2. It demonstrated the close relations between vulvitis in virgins and true gonorrhœa. The child was admitted into hospital on January 5th, 1892. She had suffered from discharge for a fortnight; it was free, tenacious, and greenish yellow; the vulva was acutely inflamed. On the ninth day after the commencement of the discharge a painful swelling appeared in the right radio-carpal joint. On admission the wrist was red, tender, and much swollen. There was absence of fever, urethritis, albuminuria, and cardiac or pulmonary complication. It appeared that there was no reason to suspect venereal taint of any kind. The discharge was carefully examined, and gonococci discovered. Sublimate lotions, and painting of the parts with a 5 per cent. solution of nitrate of silver soon cured the local discharge. After fifteen days of antiseptic treatment no more gonococci could be found. At the same time the articular complication subsided. Opinion is still divided, but many authorities deny that the gonococcus is a specific germ, and declare that they have detected it in the vulvitis of virgins.—*Ex.*

ARMY AND NAVY.

FROM JANUARY 22, 1893, TO JANUARY 28, 1893.

Captain Louis W. Crampton, Assistant Surgeon, U. S. Army, now on leave of absence at Los Angeles, California, will report in person to the Commanding General, Department of Arizona, for such temporary duty at Los Angeles, California, as may be required.

Leave of absence for four (4) months, on Surgeon's certificate of disability, is granted Captain Freeman V. Walker, Assistant Surgeon, U. S. Army, on condition that he spend the period of leave as a patient in the Army and Navy General Hospital, Hot Springs, Arkansas.

Pharmaceutical Products of the Farbenfabriken vorm Frieder Bayer & Co

Sulfonal=Bayer

induces sleep, free from narcosis, and sequelæ. It acts purely as a hypnotic and claims no analgic powers. Sulfonal is also of the highest value in the neuroses and is largely employed by neurologists. It is a safe remedy and its continuous use does not give rise to a drug habit. Sulfonal must be given according to directions. (*Supplied in ounces.*)

Salophen

is a new salicylo-phenolic derivative said to be so combined, chemically, as to constitute a safer and more effective remedy than either of its components, or any analagous preparation. The reports refer in the highest terms to its value in rheumatism and allied affections. Competent observers recommend it for extended trial. (*Supplied in ounces.*)

Europhen

is a complete substitute for iodoform and is a cicatrisant of special value in specific lesions, catarrhal and ulcerative diseases and all surgical conditions formerly treated by the latter preparation. It has five times the covering power of iodoform and forms an impervious coating over denuded tissues. Europhen has a faint, agreeable odor resembling that of saffron. (*Supplied in ounces.*)

Phenacetine=Bayer

continues to justify the high praise of physicians, and it may properly be considered as the best of the modern antipyretics and anodynes. In *la grippe*, rheumatism, migraine, neuralgia, etc., it is a prompt, safe and effective remedy. Phenacetine, unlike the secret mixtures announced as analgesics and antipyretics, is a true organic derivative. (*Supplied in ounces.*)

Aristol

is now widely used as an agreeable and effective dressing in all of the operations of major and minor surgery and in dentistry. It is invaluable in ulcerations of all kinds, and in burns, blisters and bed-sores. It adheres closely to mucous membranes and wound surfaces. (Aristol and "Europhen-Aristol," a combination of both remedies are supplied in ounces.)

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Now Ready. Price, $5.00, Cloth.

THE EARLY TREATMENT OF CONGENITAL CLUB-FOOT.

SAMUEL MARDIS HOGAN, M. D., Union Springs, Ala.

In presenting this subject I do so, not for the purpose of advancing any new theory as to the causes of these deformities, nor for the purpose of introducing any new or original line of treatment, but to endeavor to awaken an interest in these unfortunate cases which will result in their obtaining earlier treatment and more speedy and permanent cure.

In order that we may fully appreciate the importance of this early treatment we should remember that immediately after birth not only the ligaments and tendons are soft and easily stretched, but even the tarsal bones are undeveloped and can be moulded into proper shape. At this age, too, the growth is rapid and will aid very materially in overcoming these deformities after we have adopted a course of treatment suitable to the case. If, however, we neglect the treatment of these cases, which is so frequently done, there will be defective nutrition of the parts and a changing of the bony structures that may defy all of our resources to rectify. This being the case, it is certainly the duty of the attending physician to institute this treatment immediately after birth, as every day that it is postponed will be valuable time lost, for the effects of the pressure on the nutrition of the parts will be rapidly manifested. Structural changes will soon take place, which will complicate the treatment very materially and may even require an operation with the knife. It is true that a tenotomy may be required even after the best directed efforts, but it will be an exception and an exceedingly rare one. In making this statement, I know there are many eminent surgeons who contend that every case should be cut, and notably among these is Dr. W. E. Balkwell, of London, who, in an article on this subject, read before the 9th International Medical Congress, says:—"The child is brought to you at from two to three weeks old, and you have to decide when to operate, for operate you must; no extension apparatus is of any permanent good."

Edmund Owens, M. B., F. R. S., who also is a surgeon in this same home of the specialist, takes an entirely different view, and says in his book on the "Surgical Diseases of Childhood:"

"The plaster-of-Paris method enables us to treat the club-foot of a tender infant with security and success and without the expense of a mechanical apparatus requiring daily attention.

Thus, children may be dealt with in the out-patients' department of a hospital or in the out-lying districts of a country practice, with as much convenience and certainty as if they were inmates of a hospital."

In our own country the majority of our most successful orthopedic surgeons hold that a tenotomy should not be performed until it was absolutely necessary. This question will be discussed further on.

The question now arises, how should we proceed with the treatment, and in the event of failure, when should we resort to tenotomy?

All infants should be carefully examined immediately after birth, and if a club-

foot be found the nurse should be shown and fully instructed *how* to manage the case for several weeks. Three or four times a day the foot and leg should be gently but thoroughly rubbed and kneaded and the foot and heel straightened. This should be done systematically for three or four weeks, when it will generally be found that the foot can be placed in a correct position with very little force and without interfering very materially with the circulation. Then a plaster-of-Paris dressing can be applied and allowed to remain ten days or two weeks, when it should be removed, the foot and leg bathed in warm water, well rubbed and kneaded and the dressing again applied. This may be repeated for several months, or until the contractions have been entirely overcome; or it may be advisable, after a few dressings, to split the plaster-of-Paris dressing in front and have the foot taken out every day or every four days, and after being attended to it can be replaced and easily secured with a roller bandage. This dressing can also be easily arranged so as to use the artificial rubber muscles of Dr. Sayre, if it should be thought advisable to do so. At no time, however, should the plaster-of-Paris dressing be applied so as to affect injuriously the circulation or produce discomfort or pain, and we can generally avoid this by first applying a soft, thick sock, or a roller bandage of some soft, thick material, leaving the toes exposed, as suggested by Dr. Owens, and then applying the plaster bandage which should be done quickly and smoothly, the foot being held in the straight position until the plaster has firmly set.

The time may come, however, when after carrying out this line of treatment, even faithfully and intelligently, the deformity has not been relieved, and we will then have to decide whether to operate or not. To decide this question, Dr. Sayre says:

"Distortions or deformities which are the result of contractured tissue, can only be removed by forcible rupture of the same, or by cutting before traction is applied.

A *contracted* tissue is one simply shortened but which can be elongated by careful, continuous and judiciously applied traction and manipulation, and therefore does not require to be divided. A *contractured* tissue is one which has undergone some changes of structure in the fibrillæ of the muscles, and which cannot be elongated or stretched unless the tissues are severed or torn, and therefore sections in such cases are absolutely necessary. Mr. Little, of London, describes this condition as one of structural shortening. In order to determine which kind of tissue we have to deal with he lays down the following rule:

If in any case of club-foot or other deformity we stretch the shortened parts to their utmost tension by manual force or mechanical aid, and when the parts are thus stretched we suddenly add to the tension by pressing with the thumb or finger on the part thus stretched, or by pinching the stretched tissue between the thumb and finger, and if, by either of these acts, we produce a reflex spasm or sudden shivering of the whole body, the muscle, tendon, or tissue thus yielding, the *reflex spasm is contractured*, and cannot be elongated without the severing of its fibres."

This teaching of Dr. Sayre has not been fully adopted by the profession, but I know of no one who denies its correctness and, as a rule, his opinion on this subject is entitled to the fullest consideration.

Dr. Edmund Owens says: "If, after some weeks of simple plaster-of-Paris treatment, the position of the foot, though improved, be not entirely corrected, if there remain considerable inversion of the sole and some drawing up of the imperfectly developed os calcis, a tendon must be divided."

There are yet some other conditions that must be eliminated before we proceed to cut. If there is any irritation of the clitoris it must be relieved by local application or excision, or if there be phimosis circumcision should be performed, as the fact has been fully settled that it is almost, if not entirely, impossible to cure a case of club-foot with either of these conditions existing.

About two years ago I had a patient with congenital talipes equino-varus of the right foot, in which I commenced this treatment immediately after birth. The mother and child left as soon after her confinement as she was able to travel, and I saw no more of the case until he was about four months old, when she returned with him for further treatment, as improvement seemed to be very slight.

Upon examination I found both feet and legs to be of nearly the same size, and

very well developed. If he was the least excited it was almost impossible to straighten the foot, but whenever I could attract his attention, and get him in a playful mood, it would take very little force to overcome the deformity. This satisfied me fully that there was some irritation somewhere that was keeping up, or at least intensifying these contractions and, as Dr. Sayre and other surgeons had frequently reported such cases, I naturally examined the penis for the cause and found a phimosis and an adherent prepuce. I did a circumcision and liberated the adhesion after which improvement was rapid and his recovery seems to be perfect. In this case I should have most certainly operated had I overlooked this source of irritation.

When we have fully decided that an operation should be done we must then decide where it should be done, and at this point Dr. Sayre lays down this rule:

"While the patient is anæsthetized put the parts under consideration upon the stretch to their fullest extent, and while thus stretched press with the thumb or finger upon the tendon or fascia thus stretched, and if this additional pressure produces reflex contraction, that tendon or fascia must be divided, and the point of pressure producing spasms, is the point for operation."

In performing a tenotomy it is important to have a blunt-pointed tenotome, so as to avoid injuring important blood-vessels and nerves; still we can use a sharp-pointed one to puncture the skin and the sheath of the tendon if it should be preferred. The knife is introduced flatwise until it enters the sheath of the tendon, when it is passed under the edge, turned upwards against it and the tendon severed by being pressed upon it; the knife is again turned flatwise and removed, pressure being made with the finger along the track to avoid the entrance of air, and the wound is hermetically sealed with rubber plaster. All of the tendons and fasciæ are cut necessary to enable you to put the foot in proper position. This should be done immediately, and the dressing applied so as to retain in position until the wounds have healed, and the bloody serum or lymph that has exuded between the cut ends of the tendon becomes organized, which will usually take place in about two weeks.

For this dressing I still prefer the plaster-of-Paris, although there are many surgeons who prefer others, and each of them can be applied with more or less success. Those dressings, however, that are made with adhesive plaster should usually be avoided, as they are so liable to irritate the tender skin of the infant.

The usual point for cutting the tendo Achillis is just above its insertion into the os calcis, and as the knife is introduced into the sheath and just below the tendon, there will be no danger of cutting any important blood vessels or nerves. The tendons of the posterior tibial muscle, and the flexor longus digitorum may be cut, most conveniently, just above the internal malleolus, the patient lying on his side. The operation is done on the same principles as in dividing the tendo Achillis, and the only precaution necessary is to avoid cutting the posterior tibial artery and nerve, which might be endangered by carrying the knife too deeply. Or the tendon may be cut below the ankle in its passage to the scaphoid bone. The tendon of the tibialis anticus will be found in front of the ankle where it may be felt as a tense cord, lying somewhat nearer the internal malleolus than in its natural position, and where it can be very easily cut without danger, as the anterior tibial artery lies external to it.

The plantar fascia is to be divided in the same manner as we divide tendons,—by passing the knife under and cutting outwards, and it may be necessary to divide it in the posterior portion and opposite the metatarsal bone of the great toe. Other tendons and fascia may be so contracted as to need division. When they are put upon the stretch they are generally readily detected, and can then be divided.

After division of all tendons, fascia, etc., that may be needed to straighten the foot; after healing of all wounds, and after the divided tendons have been reunited, it will still be necessary to keep the foot in a proper position by means of the plaster-of-Paris dressing, or some of the many other forms of braces, splints or shoes that have been devised for such cases. In no instance should we relax our efforts to develop the muscles by daily friction, massage, electricity, etc., until the deformity has been permanently removed and our little patient is able to walk perfectly with an ordinary shoe.

I have purposely avoided going into a detailed account of the various appliances for such cases because I believe, if the treatment is commenced immediately after birth and faithfully carried out, you can accomplish with the plaster-of-Paris dressing, and artificial rubber muscles when necessary, everything that could be done with the most expensive orthopedic appliances, and with much less trouble.

THE PHYSICAL IMPORT OF VARIABLE ACHROMATOPSIA; AN ORIGINAL RESEARCH.

JOHN EDWARD PURDON, A. B., M. D., Tampa, Florida.*

The title of my paper is rather a formidable one, but shorn of technical language, it is a condensed expression for the implication that there exist certain cases of functional nervous disturbance in which variability of the color sensibility is a prominent feature, and that such variation is accompanied by changed mental and physical conditions.

Color blindness proper, a congenital affection, does not directly enter into the consideration of this class of derangements since the color vision in all my cases was at times perfect. Indeed the sharpness of this function was the inlet by which alone I could test the nature of the changes that occurred from time to time in the persons under observation.

The name of Mr. William Crookes, F. R. S., the celebrated chemist, is well known and his experiments in the line of psychical and spiritualistic research are some of the most accurate on record. The persons named in this paper as furnishing valuable physiological data were some of those with whom he made his most widely published and most startling observations. I have in my possession a photograph, prepared by Mr. Crookes himself, in which he appears with a duplicate of one of the sisters of the family I am about to describe, leaning upon his arm, his own account going to show that her natural body was at the same instant lying in a state of trance behind the curtain before which he was standing with her double leaning on his arm. I do not here offer any explanation of the *modus operandi* by which this ethereal body was produced, that being beside our present purpose; but I do offer what I regard as of much more importance to us as physiologists, namely, accurate notes taken regarding the state of that most complex but most directly presented sensorial function, vision, under circumstance directly parallel to those holding when Mr. Crookes obtained his physical data from members of the same family. No one who is inclined to place even a very small amount of trust in me as an observer will feel justified in ignoring the value of these case notes. If these are of no more value than to show that apparently simple sensorial entities are in reality very complex—being constructed out of simpler elements of feeling and so liable to disturbance on account of the different possibilities of arrangement of such elements in time, number and order—the research is of certain value from an educational point of view. As a practical matter the inquiry is also useful, for it tends to show that under conditions of nervous disturbance and specific excitement the natural signs and landmarks of objective nature are interfered with. The research shows that the colors so familiar and so fixed may vanish for the time being without interference with the general consciousness or decadence of the intellectual powers, to be restored after a time to their full recognition as permanent elements of healthy sensation.

But it is as a step into the mysterious region of the unknown, between which and us the sensorial barriers become broken down on occasions, that I attach value to such an inquiry. In a word, the ladies whose sensorial disturbances I record in this paper were what are called *mediums* or *psychic sensitives*, who have been repeatedly certified to as producing the most genuine and startling manipulations of an unknown power by Alfred Russell Wallace, the great evolutionist, William Crookes, the celebrated chemist and physicist, and many others distinguished in art, litera-

*Surgeon Major, Retired (British Army.)

ture and science. Anything of a physiological nature, out of the common, during and after such manipulations must be worth recording and I hope will be my excuse for venturing to present a subject so far out of the beaten track.

During the last three years I have been bringing before the profession, through two of the leading medical societies of the South, certain physiological and psychical matters which I believe to be calculated to throw light upon that mysterious department of psychology which goes under the name of "Psychical Research." On the present occasion I have selected the subject of variable color vision as being one which was urged upon my attention from the fact that I found its most marked indication in the members of a family well known to students of the occult, and who, some fifteen to twenty years ago, were regarded as some of the best mediums in England for the manifestations of the mysterious psychic force which has been the great puzzle and paradox of this generation.

In the middle of the year 1871 I commenced the practical study of psychic science and some months after, I had my attention called to peculiar periodical variations of visual functions in the case of a young lady *sensitive* with whom I was experimenting. I perceived that she suffered from what I afterwards found was described by Charcot as the hysterical eye, or, at any rate, that her case was related to the latter. For the greater part of each month she suffered from weakness of one eye with loss of accommodation and imperfection of color vision which, however, were both corrected by a 7 or 8-inch minus glass. She also perceived black bands or rings drawn on paper to be thickened and doubled in a certain uniform way when observed through the uncorrected eye, although the sight of the other eye was very good. As this young lady was at that time becoming famous as a medium I eagerly embraced every opportunity that offered to study such cases as hers in the hope of finding some clue to the nature of the changes that take place in the cerebral machinery whenever there were present manifestations indicative of the activity of psychic force. I noticed that at a certain time each month both the power to manifest the special psychic activity and the abnormal vision disappeared together, leaving the inference to be drawn that abnormal color and ray vision and the psychic potentiality co-existed in her case and most probably were related in consequence of a strained condition of certain parts of the brain to be determined by other observations.

Further experience tended to confirm this view, for I found in the case of this young lady, during actual manifestations of great psychic power, a total disorganization of distinct color perception and discrimination while the evidence of brain strain and congestion was furnished by profuse nose bleeding coming on during the actual exercise of the psychic power. My attention having been turned in this direction I found several instances of analogous color vision disturbance in patients of mine who were haunted by subjective spectral figures not dependent upon drink, opium or similar exciting causes. I think I may safely say that in all these cases the cardiac innervation was imperfect—a sign of the general condition of the nervous system.

Some years after I first noticed the above relations I had good opportunities of studying the vision pecularities of two sisters of the first mentioned medium, both bright and intelligent young women, who did their best to assist me in my research. The elder of these sisters, Miss K. C., was affected in the left eye, generally corrected by a minus glass as in the case of her eldest sister. The younger, Miss E. C., was affected in the right eye, generally corrected by a plus glass. This interesting contrast was verified again and again. Their ages were 24 and 18 years.

In my examination of these girls I used Holmgren's wools and colored glasses of many shades, and the colors were obtained by passing polarized light through doubly refracting crystals, the latter being very convenient for the study of complementary colors and the variations occurring in the perception of the same.

In submitting the following notes I wish them to be regarded as an account of qualitative experiments made under conditions quite unfavorable to qualitative and more, properly speaking, scientific observations. I can at any rate vouch for them as representing the facts and as fully supporting my trust in the value of similar experiences with other persons of the mediumistic or sensative temperament.

I can positively say that I have never perceived a gross contradiction corresponding with an attempt to deceive. Order in disorder, for the time being, is what I have observed. Any new departure, corresponding to some fresh peculiarity of the sensitive organization, had only to be followed up to be identified as a member of a class.

April 29th, 1883, Miss K. C., a wonderful medium for all kinds of psychical manifestations, was examined with the double image prism previous to *seance*. She could see with the left eye but one image of a pencil mark ring on white paper—that one which was most refracted. She placed the point of a pencil a good way outside the circumference of the circle when asked to put it exactly in the centre. As the paper was moved the ring was unstable in its position. The prism showed two rings in the ordinary manner to the right eye. After the *seance* she could not see at all with the left eye. The right eye remained unaffected.

Miss E. C., before the *seance*, saw the two images through the double image prism, but much separated from each other. She also remarked, when she looked at the ground glass globe of the gas lamp, that one of the images, that which was most refracted, showed broad color bands taking up nearly the whole of the outline, in place of the normal mere edging of color.

May 2nd, Miss K. C., could see only one image through the double image prism held to the left eye. When the eye was supplied with a seven-inch minus glass she saw both images quite well. An experiment was then made with plates of selenite between two Nicol's prisms. The color of the purple and greenish yellow selenite were called blue and yellow, but when the true blue and yellow selenite was placed between the two Nicol's prisms the colors were not recognized at all. Thus it appears that red and green, which were components of the purple and greenish yellow, were unperceived in the first pair of colors, while the blue and yellow, the *inferred* perception after such abstraction, were not perceived when *directly* presented in the second pair of selenite colors. After the *seance*, which was a very good one, the medium could not see with the left eye ; the correcting concave glass, which was useful before the *seance*, having, after it was over, no effect in restoring her sight. The circulation, judging from the radial pulse, was weaker on the left side than on the right after *seance*, and neither ring could be seen through the double image prism.

Miss E. C. was examined before the *seance* with the double image prism and also with the selenite plates. She saw the two images correctly and also the colors, but afterwards, though she could see the two images through the prism she had lost all sensibility for color on the affected side. Both the young ladies were examined with the colored wools after the *seance* and both had lost all power of distinction.

A careful observer called my attention to a circumstance she had noticed and which had a bearing upon the variation of color perception in the case of Miss K. C. On the fourth of May, after walking through town and feeling tired she was affected with transient right hemianopsia; that is, she saw with the left half of each retina, the other half being but little responsive to the stimulus of light, or rather the visualizing centers in connection therewith. But the dark half-field proved on trial to be more marked for the right eye than for the left. When looking at a face she saw only half of it, but she could see distinctly the whole of a bright gas flame. With the left eye she could see a shaded half face, the other half being distinct, while with the right eye she could see only the half face, the other half being perfectly blank. When examined, the purple and yellowish green selenite being placed between two Nicol's prisms, the left eye saw the colors correctly, but to the right eye the red-violet or purple was reduced to blue, and the greenish-yellow to yellow; that is to say, the red was cut out in one case and the green in the other. Shortly after the examination, while moving about, she got a headache across the eyes, when on trial the hemianopsia had disappeared and the colors were the same exactly to the two eyes.

This lady at times, when similarly exposed to the sun and to fatigue, had become temporarily aphasic, evidently on account of irregular circulation in the cerebral cortex. Physiologically speaking, her case was in many respects an exact

parallel to those of the psychic mediums here described, and therefore, calculated to throw some light upon them.

May 6th Miss K. C. was examined in good light before the *seance.* She had remarked while out walking with me that the red and yellow tulips appeared to her as "gray." Examined with the colored wools—red, dark red, blue, dark blue, light blue, yellow and blue green were all called "gray." A 7-inch minus glass corrected the achromatopsia completely. When using the double image prism she saw but one ring with the left eye, but with the minus glass added she saw both rings. When a beam of polarized light from a Nicol's prism was passed through plates of selenite and the double image prism added to complete the combination, she saw the double beam in complementary colors with the right eye, its normal appearance, but to the left eye it showed as a single colorless beam. This was true for the blue-yellow selenite, and also for the red-green, or more properly, blue-red and yellow-green; a single colorless image was in all cases perceived. When, however, the left eye was armed with the 7-inch minus or concave glass, the vision of the left eye was exactly the same as the right. After the *seance* (and I may remark that all the *seances* here referred to were satisfactory in the way of manifestations of extraordinary activity,) she could not see at all with the left eye, neither color nor ray vision remained. The glass before so marked in its effect did not restore the color of the wools, which were all described as "grays."

Miss E. C. was examined the same day. She called the green, blue and yellow wools "gray." Dark blue was called very dark gray. The cherry red and dark red she called "dark red" and "very dark red." With the double image prism both eyes behaved alike, vision being normal. A check experiment was then tried. On overlapping one of the images of a piece of green glass looked at through the double image prism, by one of those of a piece of red glass placed near it, both being held up against the light, she did not perceive the change that under ordinary circumstances is due to the superposition of lights of different colors; she simply experienced the sensation of redness, the green being entirely absent from her perception. The images of blue and yellow glass overlapped appeared as "gray" without any change being noticed. The eye was then reinforced by a strong convex glass and she saw all the colored objects when brought to a distance of four inches from the eye—the green required to be brought nearest. Outside of that distance the red alone was seen as a diffused light red. When tried with the selenite plates she saw the red-violet and yellowish-green as violet and yellow using her sound left eye, but with the right eye, that which was the peculiar one, she saw only the red or red-purple shade, the yellowish-green complementary being entirely absent.

This young lady was examined after the *seance*, during which she was for a short time "entranced." It was found that she had lost all color sensation on the left side. The double image prism showed double images without color; the wools were all "gray" to the left eye. She remarked that the double images of a pencil mark ring as seen by the left eye appeared much larger than those seen by the right eye. They had to be brought much nearer to the eye before their circumferences touched than in the case of those seen by the right eye; say, about five inches in the former case, and ten in the latter. Before the *seance* this distance was the same for both eyes, as I had noticed after careful observation.

May 27th. Before the *seance* Miss K. C., in day light, saw through the double image prism two images when using the weak left eye, though she could not perceive the colors of any of the wools offered for inspection. The sight of the right eye was quite normal. After the *seance* she saw but one image of a ring drawn on paper through the prism when the left eye was used. The concave glass corrected the defect and enabled her to see both. During the *seance*, which was held in the dark, and where many lights were seen flitting about, she remarked that she could not see the lights doubled by the prism. She over and over again said she saw the lights very small and single, and this she said was the case with the two eyes. While examining her after the seance and while her weak left eye was corrected with the concave glass, to enable her to see the double image of the ring, pressure was accidentally made on the right eye-ball, that eye being closed at the time; she immed-

iately remarked that she saw four images! This extraordinary observation was repeated again and again with the same result. These images did not fade out as the prism was turned round. Before, when she saw the second image through the concave glass, one image faded out as the prism was turned. On the same occasion Miss E. C. could see the double image through the prism before and after the *seance.* She saw the colored wools somewhat better than usual; she could see red pretty well, both dark and light, but she called the blues "greens," and the yellows "gray," During the *seance*, she declared that she saw the lights which appeared in the dark, room double, but this proved on examination to be in all probability due to want of proper adjustment of the axes of the eyes, so as to let the rays fall on corresponding points of the retinæ; for when each eye was closed in turn the lights appeared to be single in the open eye. I merely mention this to show that rational precaution against error was always observed.

It appeared from observation that every member of the family, including the mother three daughter sand one son were more or less the subjects of abnormal color sensibility. It was ascertained that Mrs. C., the mother, possessed the following remarkable peculiarity: On being given light pink wool to match, the left eye being closed at the time, she picked out a darker pink from a group of colored wools. She was then given the same pink to match, the right eye being closed, and she picked out a very light brown. But strange to say she matched colors well when using both eyes. She generally makes choice of lighter shades with the left than with the right eye singly. There was also in the case of her son, a youth of 18 years, a difference of color appreciation on the two sides without pronounced achromatopsia, as in the case of his three sisters.

The following notes are very interesting as throwing light upon the puzzling question of deranged color vision:

Miss K. C. was examined with colored glasses on January 16, 1882. On that occasion she exhibited the remarkable peculiarity of reverse color vision for red and green. When green glass was held to her left eye, the right being closed, she at once said, "red, a nice bright red." This was said to be the same sensation as when red glass was held to the left eye, the right being closed, it was called "green." It was said to cause nearly the same feeling as when green glass was held before the right eye. The same was found to be the case after a *seance* on the 18th of January, the colors, however, being darkened, while yellow light was called "gray," and blue and yellow light "black." All the colors were restored when a concave glass was held outside the colored plate at a distance of four inches. When held closer to the eye it had no effect. These experiments were several times repeated with the same result.

On January 29th, 1892, an interesting observation was made in the case of the eldest sister with whom I had experimented ten years before, and with whom I had first studied the psychical import of variable color vision. When a plate of green glass was held before her weak eye she said the light was "gray," but immediately on its removal she saw "violet." When red glass was held to her eye she said it was "gray;" then, when it was taken away, she said she experienced the sensation "green." This may be relied on as certain. With her good eye this remarkable peculiarity was less pronounced. It will be seen that it gives the key to the reverse visions of her sister, described above. The elder sister showed what I may call semi-reversal.

It appears from these results that both red and green sensations may be excited by the same physical cause; but the special sensation is determined by the state of the organism at the time. The theory of color blindness advanced by Mr. W. Stanley Monck of Trinity College, Dublin, receives support from the above observations on reverse vision. His idea was that in true color blindness owing to a functional peculiarity of the organism the pair of complementary colors were excited together with a neutralizing effect, by the presence of the stimulus corresponding to either of them acting on the retinal expansion.

The conclusions to be drawn from these experiments appear to me as follows:

1st. Nervous states with a tendency to hysteria may be accompanied by a derangement of accommodation in one or both eyes, which is indicative of a more general defect of "attention" on the part of automatic centers of the brain, whereby the elements of sensation are generally com-

bined into higher psychical complexes. Observation with the ophthalmoscope and otherwise led me to the belief that functional inactivity depends rather upon a deficient supply of blood than upon direct inhibition. I found that forced attention restored the visual function in one of the sisters when I used a distorting instrument, "Stokes lens," to excite her curiosity when looking at small type.

2nd. The existence of this state is a predisposing cause in the manifesting of psychic phenomena, such as are usually shown by respectable mediums under test conditions, at least in the instances of the young ladies here referred to; while the nose bleeding and the aggravation of visual defects in them gave direct evidence of congestion or stasis of blood in the brain, and probably also of anæmia in varying and unknown degrees; the latter supposition being supported by the trains of objective nervous symptoms so commonly seen in the case of "mediums" during "manifestation."

3d. The actual occurrence of extraordinary psychical events being provisionally granted for the sake of an application of physiological theory, it appears very probable that the relationship of the cerebral cortex to the muscular system is profoundly modified, and to such an extent that psychical states find other modes of expression than those depending upon the mechanical influence of a visible and tangible intervening substance, the nervous system being thereby placed in a more direct relationship with the space content.

The correlation of the visual and muscular systems being found by observation and experiment to have been interfered with, it is allowable to speculate upon possible manifestations of physical activity in which heat does not play so prominent a part on the physical side of the sequence, other modes of vibratory action taking its place, with a corresponding change in the psychical chain. There is a complete analogy afforded in the region of mechanical philosophy when physicists attempt the direct transformation of latent energy without the intervention of the steam (heat) engine, muscle being a heat engine and the most economical that we know of.

CLINICAL LECTURES.

A CASE OF PAPULO-SQUAMOUS SYPHILODERM.

JOHN V. SHOEMAKER, A. M., M. D.,*

B. H., 28 years of age, male, single, and a laborer, gives the following history: About 6 months ago a number of blisters appeared on the toes of both feet. Contiguous blisters coalesced, formed large bullæ and his feet were for some time so sore that he could not wear shoes. Three weeks after the appearance of the vesicles papules also developed upon the feet. The lesions were of considerable dimensions, some being as large as 3 and 5 cent pieces. In a short time similar papules were observed upon the shoulders, front of chest and upon both upper and lower limbs. The vesicles upon the feet ruptured and discharged serum, but he never saw any pus.

Upon examination there were observed upon the forehead and scattered over the hairy scalp patches of a dull red color, slightly elevated above the surface and covered with thin scales. On the palms of the hand and between the fingers there were present dry fissures which, the patient asserts, began as vesicles or papules. Some of the lesions broke and discharged their liquid contents, the others were dry from the beginning. There was little tendency to suppuration, though a few were converted into pustules. The face is comparatively free from eruption. The small patches upon the forehead are situated close to the border of the hair and might escape careless observation. But below the collar bone, the trunk and limbs, both anteriorly and posteriorly, are studded with roundish or oval spots of varying sizes, from one-half inch or less to one inch or more in diameter. Some of these spots are covered with grayish scales,

*Professor of Skin and Venereal Diseases in The Medico-Chirurgical College of Philadelphia.

others are free from crusts and of a dark red color. Four or five superficial ulcers are seated upon the penis in the furrow behind the corona glands. These made their appearance about a week ago. About eighteen months ago he contracted gonorrhœa, but is not aware that he had at that time any sore upon his penis. About eight or nine days after the first appearance of the urethral discharge the man noticed the growth of a bubo in the right groin. When it first attracted his attention the enlargement was about the size of a hickory nut; it grew slowly for three or four weeks when it opened spontaneously and discharged a considerable quantity of pus. The growth was painless and did not oblige him to lose a day's work. The patient states that the bubo healed in three or four days after opening and never gave him any subsequent trouble. He does not think that his hair has thinned or fallen, and he has no ulcers or sores in the mouth, no glandular enlargements other than the bubo. He has not suffered from nocturnal bone pains. His shins are not tender.

Six months ago he had a chancre upon the left side of the glans penis. The sore was single, large, hard and dry. He does not know that it was followed by any glandular swelling in the groin. The chancre appeared about two weeks after exposure and about two weeks after the vesicles first developed upon the toes.

The patient has never had sore eyes. He states that there is some itching of the eruption when he becomes warm in bed. There is no smarting or pain. His hands are not painful when not in use, but render him unfit for work. He feels as strong as ever he did and could work were it not for the condition of his hands. His appetite is good, his bowels are regular and he sleeps well.

As often happens when we have to deal with uneducated patients the history is indefinite and, to a certain extent, confusing. The extensive eruption upon the skin undoubtedly represents a late lesion of syphilis. This, together with the fact that vesicles appeared upon the feet two weeks before what he terms chancre was observed upon his penis six months ago, necessitates the conclusion that the date of infection dates back months. Whether the man had at that time a urethral chancre, a superficial erosion which escaped detection, or a dry papule without erosion I shall not stop to speculate. At any stage of syphilis the physician is obliged to be circumspect and compare the history with the lesions. Our picture of this disease is necessarily composite, derived from the study and comparison of many cases. We must listen attentively to the history which the patient gives, but we must accustom ourselves to eliminate errors of which he is unconcious. It is reprehensible to denominate every sore upon the genitals as a chancre. At the same time we must make ourselves acquainted with the different forms which the initial lesion may assume. As a farther illustration of the necessity of close investigation I revert to the fact that at the present time, when he has not had sexual intercourse for a considerable period, a number of ulcers are situated upon the penis.

The development of a glandular swelling in his groin eight or nine days after the beginning of a urethral discharge is significant of the presence of a concealed or undiscovered chancre. This bubo enlarged slowly and painlessly for three or four weeks. The course is that of a syphilitic rather than a chancroidal bubo. The latter lesion is of an acute and painful type, pursues a rapid course and terminates in suppuration. The bubo of syphilis, as a rule, does not suppurate. The exceptions to this rule, however, are sufficiently numerous. It is true that a bubo is sometimes seen as a result of gonorrhœa, but gonorrhœal adenitis is a rare complication and is always painful.

There is no history of early secondary manifestations. The patient cannot remember having syphilitic fever or nocturnal pains. His shins are not at the present time tender. He is not aware of having had any form of eruption upon the skin until within the last six months. He does not think that his hair has thinned or fallen. He says he has never noticed the hair to come away in combing. It is undoubtedly thin, however, but he asserts that this was always the case. Though there is no actual baldness I believe that some loss of hair has attended the rash which occupies the scalp. The patient is not conscious of ever having had sores within the mouth, nor has he suffered from iritis. The rash gives rise to some itching. Itching, though not

usual in syphilides, sometimes occurs and I have, indeed, occasionally seen cases in which it was a pronounced feature. In some cases the itching is due to pressure of the clothing or some other external source of irritation and not to the development of the rash.

Osteocopic pains generally accompany the advent of secondary syphilis. They seem to have been absent in this case. At times, with or without a clear and definite history of primary disease, these pains in the bones assume an aggravated character. The writer recalls especially two instances. One was that of a young man in whom there had been doubt as to the nature of the sore upon the penis. The outbreak of constitutional syphilis was preceded by severe frontal headache accompanied by earache. The second was that of a young woman who had been upon the town, who had been treated for other forms of venereal disease, but who was not known to have had a chancre. The pains in the tibiæ were of unusual severity.

What shall be thought of the chancre which the patient is said to have had six months ago? The description here is plain and reads like that of an initial lesion. It is possible for reinfection to occur though cases of the kind are very rare. In genuine reinfection, however, the period of six weeks elapses before the manifestation of secondary disease just as in the ordinary type of the disease. According to our history an eruption preceded for about two weeks the appearance of the so-called chancre. Whatever may have been the nature of the sore, therefore, it cannot be considered as the source of the eruption upon the skin. Nor was it accompanied by any bubo. The man informs me that the first lesions he observed were vesicles and bullæ upon the toes and other parts of the feet, but that in about three weeks' time papules also made their appearance upon the feet and subsequently upon the general surface of the body. When he came under my observation the lesions were of uniform type with the exception of those upon the hands. The large elevated patches were evidently formed by the coalescence of neighboring large papules. The appearance of the lesions has already been described.

I entertain no doubt as to the syphilitic origin of this extensive eruption. That the history is not clear is not an extremely rare peculiarity. The case is remarkable, however, for the extensive and general involvement of the skin. The lesion is the papulo-squamous syphilide, or, in other words, a transformation of the large papular syphiloderm.

The large, flat or lenticular papules of syphilis is a late secondary manifestation and may not occur until the second or even the third year after infection. At times, again, it may, as in the present case, be the first cutaneous manifestation of the disease. Individual papules vary in size from a small shot to a bean and are round or oval in form. This eruption is always of an intractable character. The papules are very apt, as in the case of this patient, to appear upon the scalp and forehead, in which situations they are known as "corona veneris." They grow slowly by peripheral extension, remain stationary for a number of months and disappear by absorption, generally leaving behind them pigmentation and atrophy.

The lenticular is not infrequently transformed into the papulo-squamous syphilide, the predominant form in the case which I have portrayed. The surface of the papules or patches is covered with a thick, dry or grayish scale, which can be easily detached. After removal a slow reproduction of the scales takes place. This process may continue for years. During recovery the scales cease to form and the infiltration is absorbed.

The papulo-squamous syphilide exhibits a decided predilection for the palms and soles. In those situations the patches are often so large as to involve nearly the whole surface. They give rise to a figured condition of the skin and to considerable pain. They may also involve the nails.

The disease with which this form of syphilitic eruption is most likely to be confounded is psoriasis. But in psoriasis the scales are thicker, more abundant, of a silvery, waxy or mother-of-pearl color. They are situated especially upon extensor surfaces. The syphilitic scales are grayish, yellowish, or dirty white in hue. The accumulation of epidermic scales is the prominent feature of psoriasis. A squamous syphilide is not unusual upon the palms and soles while psoriasis rarely attacks those regions. When the epithelial scales

of psoriasis are removed a bleeding or bright red surface is exposed. The scales of the syphiloderm are easily rubbed off, leaving a dark red papular surface. The scales of psoriasis overlap the red bases on which they are situated; those due to syphilis do not completely cover the elevated surface upon which they rest; they may only constitute a sort of fringe around the margin of the patch. Psoriasis most often developes at the age of puberty. Syphilis is not usually encountered at so early an age. Other evidence can usually be obtained pointing to the presence of syphilis.

There is scaling in squamous eczema, but this affection bears no close resemblance to the squamous syphilodeum. The primary lesion of eczema is erythema, vesicles or pustules; the scales are thin and easily detached. They are seated upon a bright red surface and are more frequent on flexor or extensor surfaces. Chronic eczema of the palm exhibits more thickening and is attended by burning and itching sensations. The patches of squamous eczema are irregular in shape and blend imperceptibly with the surrounding skin.

The treatment of this case is that of secondary syphilis. The man is strong and well nourished, has a good appetite and sleeps well. Special tonic medication is, therefore, not needed. His system should be brought as speedily as possible under the influence of a mercurial. The special form in which the metal should be administered is a matter of secondary importance. I generally give the green iodide of mercury—one-eighth grain in combination with about $\frac{1}{18}$ grain of tartar emetic. This amount is given thrice daily and does not cause tenderness of the gums nor diarrhœa. I increase the dose until a fourth or a third of a grain of the mercurial is taken four times a day. A more rapid and effective method of influencing the system is by the hypodermic injection of some preparation of mercury. Many combinations have been devised for this purpose, but I have long been in the habit of using the corrosive sublimate. The solution which I employ contains four grains of corrosive sublimate to one ounce of water. It is well to begin with the injection every day of five minims of this solution and increase the dose minim by minim every second or third day until improvement is manifest or the constitutional effects of the drug are produced. The dose may then be reduced and the influence maintained by smaller quantities until recovery.

COMMUNICATIONS.

REFLEX DISTURBANCES IN THE CAUSATION OF EPILEPSY*

WILLIAM C. KRAUSE, M. D., Buffalo, N. Y.

Epilepsy must be considered as a complex symptom arising from a multiplicity of causes. That form of epilepsy due to peripheral reflex irritation becomes every day more and more realistic to me so that I am fast becoming a skeptic on the question of idiopathic spontaneous epilepsy.

The tendency of the times is to find a cause for every effect, and to regard with suspicion every effect that has no appreciable cause. If after an unsuccessful attempt to find some provocative agent and the epilepsy, dating from infancy, is coupled with an inherited neurotic temperament, then I am satisfied with the term "idiopathic." This designation however signifies but little, except perhaps to believers in spontaneous generation; it does not imply that some cause may not be, or may not have been present, only that we are unable to find it and so put a coat of scientific varnish on an otherwise faulty and unpolished conclusion.

We learn by studying the fundamental laws of nature that all matter is in a constant state of motion and anything that hastens or retards this vibration produces an equivalent amount of heat or heat values. Moreover, that force cannot be annihilated. If destroyed in one form it reappears in another without suffering any loss. Apply these laws to the human sys-

*Read before the New York State Medical Society, Feb. 8th, 1893.

tem and we can account for reflex epilepsy perhaps as follows:

A perfectly normal nervous system holds sway over a healthy vigorous organism. The functions of secretion, excretion and assimilation follow closely the physiological laws governing them. The result of these metabolic forces means work, either mental or physical or both, along some clearly defined channel. The whole system then, is in a normal state of motion, each fibre and gland working faithfully and assiduously to keep the structure in a state of perfect equilibrium. Perchance a nerve trunk or nerve terminal is subjected to some insult causing abstruction, retardation or interference of its molecular vibration.

Accordingly heat units or heat values are generated, because of this irritation; are reflected to the great heat centre—the brain, and there converted into heat equivalents such as pain, tremor, spasms, etc., referable to the seat of the initial lesion. The process continuing indefinitely, without relaxation, accumulation of heat values ensues and an explosion of nerve force is the result.

Reflex epilepsy means therefore a state of irritation of the cerebral centres, produced not by a central, but by a peripheral lesion. The peripheral irritation is reflected to its cerebral centre in the same manner that a central or cerebral lesion reflects the irritation to the extremities. Thus in Jacksonian epilepsy a lesion pressing upon the motor centre of the right arm is manifested by spasms beginning in that arm; and likewise in general epilepsy the point of origin of the aura denotes most probably the seat of irritation in the certical centers of the brain.

The line of demarcation between reflex and traumatic epilepsy should be sharply drawn. In the latter the irritative lesion is directed and local, the result of a trauma to the cranium and the consequent convulsions are in a degree amenable to the surgical art; still not to such an extent as was claimed by observers a few years ago. This form of epilepsy will receive worthy attention in a subsequent paper.

It is true that not every scar, ingrown toenail, phymosis, pinworm or what-not begets reflex cerebral disturbance, or else this form of disease would be as wide spread and prevalent as was the itch during the middle ages. Therefore some other property or idiosyncrasy must be present in order that the conditions be fulfilled. A neuropatic disposition either inherited or acquired is the *sine quâ non* of this symptom-complex.

This need not necessarily be present at the time the irritation commences, but may be saddled upon the system as the result of the tireless, unceasing effort of the brain to counteract the nerve strain. The patient in a short time becomes peevish, excitable, anæmic and the parents will state that the child has of late become nervous. In those cases of an inherited neurotic disposition the convulsive attacks appear much sooner after the advent of the irritative lesion, and as a rule the epileptic habit is early and fast engrafted upon the constitution. This irritation once relieved or remedied the habit still persists in these latter cases and, to all intents and purposes, the patient has the appearance of suffering with idiopathic epilepsy. When such is the case the nature and origin of the diseases are almost impossible to ascertain, and the epilepsy is classified as spontaneous or inherited.

The question may now be asked, what shall we look for in deciding the immediate causation of reflex epilepsy? As a rule, whenever practicable I have the patient remove all his clothing and examine him thoroughly, beginning with the feet.

Ingrown toenails, corns and callouses are not infrequently the cause of epilepsy. Scars about the limbs, disorders of the genitalia, incomplete descent of one or both testes are some of the causes in youth. In girls, the condition of the clitoris and vulvæ should be ascertained, also whether there is incontinence of urine, or the presence of oxyurides in the vagina or rectum. Hare in his monograph on Epilepsy says, "it may be laid down as a fact, that in all cases in girls in which epilepsy of unknown cause develops, the vagina should be examined for the presence of any pin worms which may have emigrated from the rectum." The condition of the rectum should not be overlooked, but carefully explored especially for ulcers and irritating hemorroids.

Coming to the head we have an extensive field for examination. The mouth nose, ears, eyes and scalp may all harbor seemingly trivial disturbances which, un-

der other circumstances, would pass unheeded and unnoticed. Disorders of dentition, such as faulty direction in the growth of the teeth, hidden fangs, caries, neoplasms in and about the buccal cavity, retained foreign bodies in the pharynx, scars,—the result of ulcerative or specific processes about the tonsils, tongue and larynx, palypi and foreign bodies in the nose and ears, disorders of refraction, in short whatever can impinge, either directly, or indirectly upon nerve trunks or nerve filaments, other conditions being equal, may produce reflex symptomatic epilepsy.

These then are some of the more common of the external causes and to discover them is easy—very easy as compared with the probable internal causes. No doubt you are all acquainted with the stomach as a very frequent contributor to this subject. Those of us who pay special attention to nerve diseases receive many cases labelled epilepsy due to stomach troubles. The round worms of the intestines are a common cause and have been recognized as one of the most prolific factors in the etiology of this disease. Disturbances of nearly every internal organ have, according to various writers on this subject, been at one time or another instrumental in precipitating this. There are two organs however in this list of causative agents to which I briefly invite your special attention, namely the stomach and the urethra.

Two of the most important causes known to man, lay or professional, the stomach because it receives not only that which nourishes and sustains the human economy, but nearly every thing else that cannot be conveniently served in some better way,—the urethra, because through it flow "little drops of water" mixed with "little grains of sand,"—at times another fluid coming from another gland. In a boy—and not necessarily such a small boy either—what two organs are subjected to more abuse and refuse, and what two organs call forth more care, repair and dispair? Surely none.

The importance of the stomach as a primary etiological factor is in my opinion over estimated. I will not deny that in some cases the ingestion of indigestible matter invites convulsions, and that after a thorough emesis or purge the spasms disappear. Many patients tell their physicians that such was the cause, the starting point of the first attack, and the physician confidingly tells the specialist the same story. They will further testify that they can foretell the onset of an attack by the voracious appetite, peculiar sensations at the pit of the stomach, vomiting of watery fluid and the desire to eat anything and everything that comes within reach. Put this patient on a bland or exclusive milk diet and keep him on it for months—give him pepsin, trypsin, papoid and *strap oil until he turns blue in the face* and, if your experience is similar to mine, he will continue to convulse and froth at the mouth, and you are fortunate indeed if his parents do not become similarly affected. I believe that in many of these cases we are on the wrong trail and must seek the cause elsewhere. The symptoms denoting gastric affinity are not so much epileptic-genic as epileptopathic. These disturbances, as the patient and parents declare, hold a close relation to the paroxysms and I believe they are only localized epileptic attacks or epileptic equivalents. The increased tension in which the nervous system is held just prior to an attack stimulates the gastric glandular system through the sympathetic and pneuma-gastric nerves calling forth an abnormal secretion of gastric fluids and the flour of gastric juice means an appetite. The stomach naturally becomes tender and hyperæsthetic under such rule long continued, and anything that irritates or demands undue exercise of the function is rewarded with stern rebuke. I have the stomach perform similar antics in hysteria and general paresis, and yet neither you nor I would affirm that the gastric trouble was the cause of these ailments.

Now turn to the urethra such as is controlled by a boy from his eighth to his eighteenth year. He may live high or live low, be a street urchin or a mother's pride, a country lad or a city tough, it matters little, he is for all that a boy, and as dogs will be dogs so boys will be boys. The same old story he has eaten green apples and has had fits; he has been doctored for his stomach and strange enough the fits still persist. As he comes into your office you notice that his head hangs, his eyes are dull and sunken, his gait heavy and labored and his answers are backward and evasive. You put the question direct and with force and he admits that he has occa-

sionally masturbated—but that he learnt it from the other boys. Now instead of upbraiding and threatening him you do your duty and examine his genital organs, inside as well as outside and, in nine cases out of ten, you will find some irritation seated most generally in connection with the penis. The prepuce may be too long or too short, adherent or constricted, the frenum may be too short, causing a mild form of hypespadia, or the prepuce has never been everted and large accumulations of smegnea are present. Supposing that none of these conditions are found you have still the most important examination to make—the exploration of the urethra, and how many times is it undertaken in these cases? The boy has never had connection and hence you infer no gonorrhœa with its attending inflammations and strictures, and why waste time in such an absurd procedure. But try to introduce a No. 12 or 15 French Benas catheter and although they glide along so nicely at other times—you are beset with obstacles in passing through constrictions, evading the boy's hands and in convincing him that his urethra is anæsthetic and he does not feel any pain.

I am thoroughly satisfied that there are many disturbances present in a good boy's urethra which prompt him to vicious habits, and they in turn, if his constitution is impressionable, lead to serious nervous disorders such as chorea, epilepsy and neurasthenia. Vegetations, polyhi, cysts or other neoplasms in the walls of the urethra creating strictures, hyperæsthetic areas, low forms of inflammation, etc., are translated by such symptoms as priapasm, spasm of the urethral muscles, frequent micturition, spermatorrhœa, masturbation and sexual excesses. The influence of these morbific agencies upon the central nervous system is too well known to be here reviewed. The more a boy's urethra is examined the more I am convinced that it's not what it is cracked up to be; furthermore that a virgin urethra may be as full of strictures as his pockets are of marbles in the spring—still further that, by virtue of the morbid processes present, he may have an urethral discharge which is as innocent and inocuous as are the conditions giving rise to it. In a short period of time I have treated six boys with reflex neurosis, five of which were reflex epilepsy due unquestionably to disturbances along the urethral canal. In some of these cases, I have found the meatus urinarins surrounded by a red border or ring indicating perhaps the congested state of the urethral lining. An oscopic examination should never be omitted, for by its relations the exact nature of the lesion can be determined.

My treatment of these patients has consisted, besides the administration of the bromides, in the use of a mild galvanic current of from one to five miliamperes, each treatment lasting about three minutes weekly. In the employment of the ordinary urethral electrode I have been annoyed by several inconveniences. The olive point electrode is more or less inflexible. Besides having a metallic point, its introduction in many cases becomes difficult owing to the fact that a contraction of the urethral wall is produced through the stimulus imported to the mucus membrane by the metal. Then too, in cases of stricture, vegetations, etc., where the electrolytic action is desired, the metallic point is liable to produce injury in its passage or, when the olive is in close proximity to the sphincter vesicæ, a strong current may produce unpleasant sequelæ.

To overcome these drawbacks Messrs. Fiemann & Co. have made for me an electrode possessing lightness, flexibility and a non-metallic bulbous point. A benas catheter or bougie is encircled with a narrow steel band about 1 to 1½ inches from its bulbous extremity. This band is connected with the attachment by means of a soft copper wire extending through the interior of the catheter. The electrode is made in two sizes, No. 15 and 20 of the French scale. In all cases thus far, in which it has been used, it has given satisfaction.

All That is Necessary.

The American Association for the Advancement of Science says that the following lines are all that is necessary for the physician to learn in order to prescribe in the metric system:

1000 milligrams make one gram.
1000 grams or cubic centimeters make one kilo or liter.
65 milligrams make one grain.
15½ grains make one gram.
31 grams make one ounce, Troy.

A PORTABLE COMBINED OPTOMETER AND OPTHALMOSCOPE (OPTHALMOMETROSCOPE).

ROBERT C. MOON, M. D., Philadelphia, Pa.

Most practitioners of medicine have probably experienced at some time or other, when at a distance from their consulting rooms, the need of a portable, and at the same time an efficient set of lenses for testing the refraction of their patients' eyes. With the hope of meeting this want I have had such a set of trial lenses constructed, with an Ophthalmoscope attachment which greatly increases its usefulness. The instrument consists of the following parts:

1. A revolving disc three inches in diameter, having one blank aperture and

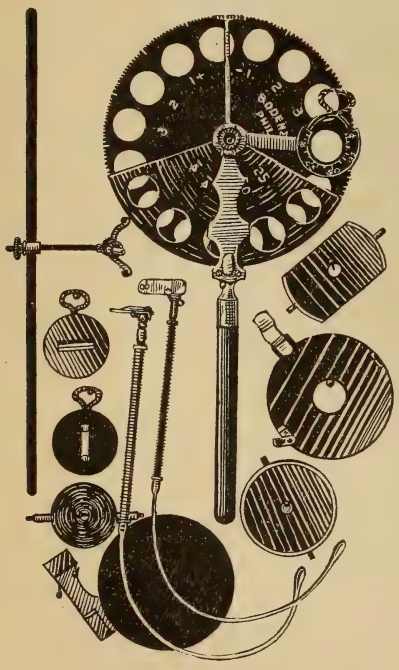

Fig. I.

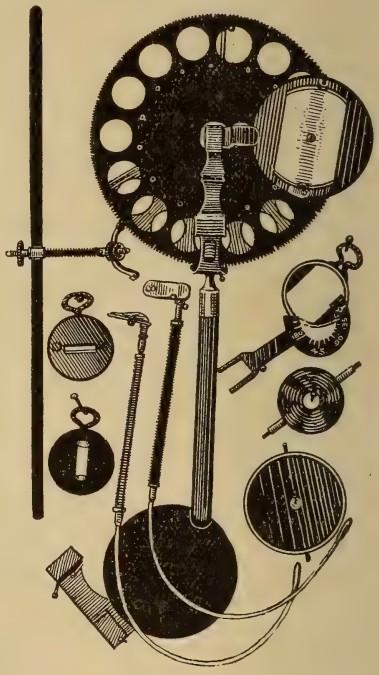

Fig. II.

carrying thirteen spherical lenses, viz.: +1, 2, 3, 4, 5, and 6 D., and—1, 2, 3, 4, 5, 6, and 7 D.; the minus series being represented in red. The edge of the disc is milled to facilitate its movement by the thumb and fingers.

2. A quadrant which is made to revolve around the same centre as the disc by means of a projecting arm with a bent extremity. It carries five spherical lenses, viz.: +0.25, +0.50, +0.75, +14, and —14 D. These spherical lenses, singly or in combination with those in the disc, give eighty-three different powers with 0.25 D. intervals up to 7 D., plus and minus, and with 1 D. intervals from 7 D. up to +20 D. and —21 D. All the lenses measure 11 mm. in diameter, and when those in the disc and quadrant are being used together, the sum of their powers can be readily determined by the addition or subtraction of the figures which are in the same line. For example, if +1 D. in the disc be combined with +0.75 D. in the quadrant, the resultant power is +1.75 D.; if —1 D. in the disc be combined with +0.75 D. in the quadrant, the resultant power is —0.25 D., and by combining —7 D. in the disc with +14 D. in the quadrant, we have +7 D. The revolutions of the disc and quadrant are controlled by spring stops, securing accurate adjust-

ment of the lenses, Either the disc or quadrant can be moved separately, or either can be rendered immovable at pleasure by means of slides fitting into notches in their margins. (Vide Fig. 1.)

3. A cell for carrying cylindrical lenses. It is graduated for every 15 degrees, and can be attached on the right or left side of the disc.

4. Fourteen cylindrical lenses separately mounted in rings, viz.: plus and minus, 0.25, 0.50, 0.75, 1, 1.25, 1.50, and 2 D. These cylindrical glasses in combination with the spherical lenses are sufficient for correcting a large proportion of the astigmatic cases which present themselves, and are so mounted that their axes can be rotated in the cell through 180°. A stenopæic slit for diagnosing astigmatism can also be used in the same cell.

The optometer thus constructed can be readily converted into a refraction Ophthalmoscope (Vide Fig. 2.) by further attaching either of the following:

5. Two ophthalmoscope mirrors, the one a circular plane, and the other a "tilting" concave mirror of 25 cm. focal length. Either of these can be swung upon a perforated plate which is fastened into either side of a box behind the disc. The plate acts as a shield to the observer's eye and when the tilting mirror is used it can be inclined to it at any desired angle. All annoying reflection from the instrument for the lenses can be avoided by placing the light on the right or left side of the patient's head as one or the other eye is being examined. As the mirrors are easily detached from the perforated plate the latter can sometimes, with advantage, be allowed to remain attached to the disc when the refraction is being tested as the size of the aperture corresponds with that of the lenses.

6. A well-balanced handle for holding the instrument.

7. One +13 D. lens, one and one-half inches in diameter, for the examination of the eye by the indirect method.

This combined Optometer and Ophthalmoscope, with its handle, is very light and portable, whilst it has been found in practice that the lenses are sufficiently large to preclude the likelihood of fallacious results from too great an exclusion of extraneous light.

Fig. III.

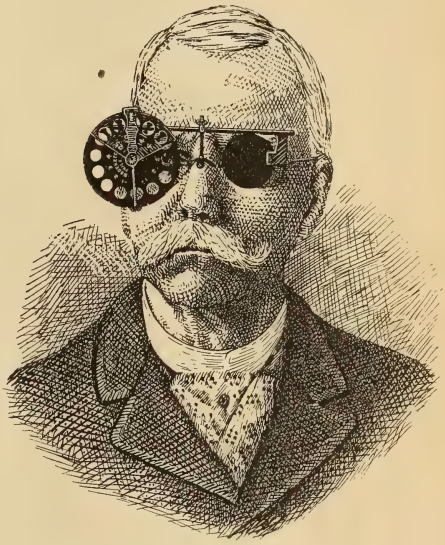

Fig. IV.

It is to be hoped that this little instrument may not only be of occasional service to the specialists, but also prove a valuable and economical addition to the armamentarium of many physicians who are debarred by the costliness of the ordinary optical outfits from investigating optical cases which present themselves in their practice. It occupies so small a space that it can easily be carried with other instruments in a handbag adding but a few ounces to the weight.

Those who desire a more complete instrument for binocular correction can have two discs, each constructed as described above, mounted upon a light frame with an adjustable nose rest and the Boden spring temples attached at the sides, so that both eyes can have their correcting lenses accurately placed in front of them. (Vide. Fig. 3.)

If it be desired a single disc with its quadrant can be mounted upon one end of the frame, and an opaque disc for covering the eye not under examination upon the other end. (Vide. Fig. 4.)

In the latest model a screw arrangement has been added to the bar of the frame by which means the lenses can be adjusted accurately before each eye *separately*, so that if there be any strabismic deviation there will be no difficulty in making the centres of the pupils correspond with those of the lenses.

When the single instrument is held in the hand during the examination of one eye the other can be covered by an ordinary eye shade.

This instrument can also be used as a Skiascope, and dispenses with the necessity of using any special disc for studying Retinoscopy, or the so-called "Shadow Test."

Any other series of lenses beside those named can be substituted if desired; more cylindrical glasses can be furnished and a special concave mirror of 8 cm. focal length for the direct examination can be adapted to the instrument. The mirror can be inclined at any angle. By means of a small Maddox rod which fits into the cell referred to above, the various anomalies of the occular muscles can be detected and prisms of a suitable size can be used for arriving at a complete diagnosis.

To sum up, the complete instrument comprises an Optometer and Ophthalmoscope, a Skiascope and a trial frame with means for testing the occular muscles, and, as the various parts are constructed separately, one or more of them can be purchased as required.

The instrument is made by Messrs. H. C. Boden & Co., Opticians, Philadelphia.

CERTAIN FORMS OF SEPTICEMIA RESULTING FROM ABORTION.*

ANDREW F. CURRIER, M. D., New York City.

The forms of septicemia to be considered are not exclusively peculiar to abortion, but may follow the termination of the pregnant state whether that has occurred maturely or prematurely. Modern antiseptic midwifery has reached nearly ideal conditions in its care of the parturient woman and her offspring at term. Assistance is almost always available to a woman at such a time, and if she enters a maternity hospital nothing is lacking, as a rule, which would minister to her safety and recovery.

How different is the situation with reference to abortion. In the first place it is an unnatural process, while parturition at term is natural and physiological. It signifies the interposition of disease or violence, and the disturbance to a greater or less degree of the equilibrium of natural forces. It is regarded by many women as too trivial a matter to require the attention of a physician and is attended with carelessness and neglect. It is probably responsible for more of the serious disease which affects the pelvic viscera of women than any other cause.

Septicæmia in the light which has been shed upon it by bacteriology signifies that poisonous elements are circulating in the blood, which are distributed more or less extensively over the body and cause serious and often fatal consequences. These elements have been found, isolated, cultivated and the culture fluids successfully used in reproducing the phenomena of the disease, microbes similar to those which were injected being found in the white blood corpuscles, the blood vessels and the subcutaneous tissues contiguous to the point of inoculation. Such experiments have been repeatedly performed upon animals, and Garré, Bumm, Bockhardt, and Schimmelbusch have performed them upon their own persons.

In septicæmia following abortion the products of conception have not

*Read before the New York State Medical Society, February 9, 1893.

been completely removed, there has been decomposition and absorption, or the introduction of poisonous elements from without. The intensity of the disease in a given case will be regulated by the virulence of the poison, the resistance of the individual and the efficiency of treatment. Two varieties of bacteria are principally efficient in septicæmia, streptococcus pyogenes aureus, and staphylococcus pyogenes aureus. They may be of variable activity, may modify each other's action, and may be modified by the action of other bacteria which under normal conditions of the body may be harmless parasites (e. g. bacterium coli commune). The resisting power of the body is a very variable quantity, differing with temperament and disposition, and modified by its surroundings.

The cases of the disease may be divided into mild, severe and uncontrollable varieties or groups; the first always ending in more or less complete recovery, the second often terminating fatally, the third being almost invariably fatal.

In the first group the abortion occurs most frequently at the third or fourth month of gestation after more or less pain and hemorrhage, and is followed in a few hours by clots and portions of the fœtal envelopes. Blood and membranous tissues continue to be discharged for the next three or four days. Then come chilliness, constipation, sallowness of the skin and anxious facial expression. The uterus will be enlarged, soft and sensitive; the os patulous and the uterine discharge offensive. The general condition will resemble that of the continued fevers of mild type. If the surroundings are favorable and the treatment intelligent, including curettage, gauze drainage of the uterus, and judicious use of salines, calomel and tonics, prompt recovery will ensue. In another class of mild cases in which the patient is neglectful of herself, the surroundings bad, and the treatment inefficient and unskillful there may be recovery after an experience with endometritis or salpingitis, and the conditions will be favorable for much trouble in the future.

In the second group of cases the symptoms are more serious than in the first, the result is fatal for some of them, while for others there is partial recovery with more or less diseased pelvic organs. In these cases there may be a history of precedent abortions with resulting induration of the uterine tissue, or of criminal operation or serious disease—such as cancer, tubercle, or syphilis, or the patient may have been so weakened by other disease, by work or worry that little resistence could be offered to the inroads of septicæmia. The course of the disease may be febrile or afebrile; there may or may not be suppuration; there may be steady progress to a fatal issue, remissions with final recovery or remissions ending in death. It is difficult or impossible to delineate exact types of the disease for there would be modifications in almost every case, but it is possible to discriminate one form in which the toxic, and another in which the inflammatory element predominates. In the toxic cases there is an initial chill without high temperature, but with small and quick pulse, frequent and shallow respiration. The facial expression is anxious and the skin sallow. There is tenderness of the uterus and its surroundings and there may be induration in the groins and at the vaginal vault. The odor of the breath is disagreeable (but I have never noticed that it is *sweetish*), the mouth and tongue are dirty, the stomach and intestines are paralyzed, the abdomen distended and sensitive, but the pain is not the cutting pain of acute peritonitis. The appetite is wanting and vomiting is distressing. When bile is vomited for any length of time I have always observed a fatal termination. There is insomnia, delirium and muscular trembling and twitching.

Treatment must be energetic from the beginning and include curettage, uterine and vaginal irrigation, oxygen inhalation, alcohol, fluid nourishment and turpentine enemata. The latter are often of the greatest value, but must not be used too often nor in too great concentration. Such treatment may cause disappearance of the grave symptoms and convalescence and recovery may ensue, or foci of infection may be re-kindled and death follow quickly. In the inflammatory cases the symptoms are severe, but they are less insidious than in the toxic. There are well marked evidences of peritonitis, or of cellulitis with rapidly extending induration in the pelvis and abdominal wall. The temperature, pulse and respiration will be febrile and fluctuation may be expected in the

vagina, rectum, gluteal or inguinal region. Incision and irrigation may be followed by relief and recovery, or the issue may be pyæmia and death.

In the third group of cases there may be sepsis and death within a few hours or days, or there may be extensive suppurative processes resulting fatally in a longer or briefer period according to the endurance of the patient. The former are absolutely hopeless, the latter nearly so. Successful abdominal sections for the suppurative cases have been reported, but they are rare.

The foregoing observations have been made on the basis that septicæmia is a disease or condition to which peritonitis, cellulitis, lymphangitis and phlebitis are subsidiary. This is in accordance with bacteriological manifestations and simplifies much that has heretofore been vague and confusing.

SOCIETY REPORTS.

THE SURGICAL SOCIETY OF LOUISVILLE.*

Stated Meeting of November 14th, 1892.

THE PRESIDENT, Dr. A. M. Cartledge, in the chair.

STRICTURE OF THE ŒSOPHAGUS.

DR. W. C. DUGAN: This little patient has a pronounced stricture of the œsophagus, a result of swallowing caustic. The stricture at first was impermeable, and in order to save the patient's life gastrostomy was performed last February at the Children's Hospital. The question I want to ask is whether it would be advisable now to close the opening in the stomach. A bougie about the size of your finger can easily be passed through the stricture, and the child is able to swallow all its food in the natural way. When the operation of gastrostomy was performed, the patient was very thin, and absolutely unable to take any nourishment at all. You will see from his appearance to-night that he has gained in flesh by being fed through the tube, and as he is now able to swallow with little difficulty, I am in favor of closing the opening. The wound gives him a great deal of trouble from irritation, there is some leakage, and the opening sometimes becomes prolapsed.

DISCUSSION.

DR. A. M. CARTLEDGE: How often did you dilate the œsophagus with bougie?

DR. W. C. DUGAN: Every three or four days.

DR. A. M. VANCE: I am inclined to the opinion that the time has come when this wound should be closed. I do not see any reason now for keeping it open, as the patient is able to take nourishment into the stomach in the natural way.

DR. W. L. RODMAN: I think there are two sides to this case. While I am inclined to agree with Dr. Vance that this fistula should be closed, yet I think, when the child begins to swallow hard substances, the stricture is likely to close again and it may then become necessary to re-open the gastric wound. This has been proven in my experience recently with a similar case at the city hospital.

DR. I. N. BLOOM: I would like to ask Dr. Dugan to give some idea of how he would treat the case after closure of the fistula; the frequency with which he would use the bougie, and the probable result.

DR. WM. CHEATHAM: Intubation is often used in these cases. I have a set of tubes for this purpose. They can be worn permanently.

DR. W. C. DUGAN: In answer to Dr. Bloom, I propose to dilate the œsophagus every week until Dr. Cheatham takes charge of the case and uses his tubes.

In regard to closing this fistula I hardly know what would be the best method. I am rather inclined to think the best procedure would be to do a plastic operation, making an incision a little lower down and tearing the stomach

*[Our correspondent explains that the delay in presenting this report was due to misplacement of Dr. Cheatham's essay. The value of the material, alone permits of its publication at this late date.—ED.]

loose entirely; that is, separate the mucous membrane and put in a puckering string.

Dr. A. M. Cartledge: I differ with Dr. Dugan as to the manner of closing this fistula. I do not see the necessity for separating the stomach, nor making another incision. I think a good result could be obtained by simply paring the edges and using Thiersch solution. I believe the fistula ought to be closed as the stricture has been dilated to such an extent that I think it will be the cause of no further trouble, for the present at least.

PATHOLOGICAL SPECIMENS.

PYOSALPINX.

Dr. W. C. Dugan: I have two specimens removed from the same patient, a pyosalpinx with abscess, and one ovary. The patient was twenty-six years of age and four years ago had her first attack of pelvic trouble which was diagnosticated as "Ovarian Neuralgia," and she was treated for that trouble. In a few months she had another attack and so on, this being the fourth. At the time of the operation she was suffering from acute peritonitis, and in the midst of her menstrual period. From the fact that the peritonitis seemed to be becoming more and more general operation was performed without further delay. The uterus was prolapsed in Douglas' pouch almost including the vagina, forcing the wall down; the adhesions were very dense and extensive, and this is the point I wish to call especial attention to. The patient has made a rapid recovery, without an untoward symptom. No drainage was used.

DISCUSSION.

Dr. A. M. Vance: I assisted in this operation and I certainly never saw adhesions so dense considering the size of the growth. We had to enlarge the original incision before it could be brought up at all. I congratulate Dr. Dugan upon the excellent result.

Dr. W. C. Dugan: This patient was taking three or four grains of morphine daiiy up to the time she was operated upon; it has not been necessary to give any since.

NECROSIS OF PUBIC BONE.

Dr. A. M. Vance: About a year ago Dr. McIntyre, of New Albany, Ind., brought to me a patient forty-five years of age, who had for several years had a fistula over the left side of the pubic bone, just on the outside of the external abdominal ring. At that time I could find nothing with the probe and advised operation as the only means of curing it, but this was declined and I did not see the patient until day before yesterday. The man came back and said he had tried a year's treatment with no benefit and desired an operation performed. Without probing or looking at it I had him sent to the infirmary and, opening the sinus, removed this little piece of bone, evidently one end of the pubic bone. It was perfectly loose and sequestrated; it was near the surface, entirely detached, and lying cross-wise in the opening. It is rather uncommon for the pubic bone to become necrosed; there is no history of injury or syphilis. The sinus was open to the detached piece of bone and had been running for four or five years.

Dr. A. M. Cartledge: Necrosis in this region is extremely rare except from injury.

Dr. Turner Anderson: This is the second case of the kind I have seen. The first was a young lady that I attended who had osteitis affecting the symphysis. She was very promptly relieved by operation and scraping.

MASTOID DISEASE AND BRAIN ABSCESS.

Dr. Cheatham read a paper on the most recent treatment of disease of the mastoid and brain abscess, the result of disease of the middle ear, and reported several cases. One, a young man who came to him with acute suppuration of both middle ears, July 28, 1892, has vertigo. I put him on appropriate treatment. August 1st, he reported with increased vertigo and great tumefaction of tissues over mastoid and tissues of right side of neck; great pain over right side of head. August 11th, vertigo increased; neuritis of right optic nerve; tumefaction over mastoid and of neck nearly gone; nystagmus. Temperature 99.2. August 13th, temperature normal. Says he feels like a two-year-old. Vertigo much less. August 15, pain in left ear. August 18th, slight edema over left mastoid; pain down side of neck and into shoulder. August 21st, vertigo so great some one has to hold him up; pain in left side of neck increasing; neuritis of both optic nerves; auditory

canal much swollen; left middle ear full of granulations. Middle ear curetted and a large mass of granulation tissue removed. August 22d, pulse 60; temperature 99; sleeps most of the time; talks well when aroused; occular conjunctiva congested and very dry; cornea very dry; pulse 60; temperature 99.5; pupils dilated; will not take nourishment; some loss of grip in right hand. He complained for several days of great pain over left side of head; slight rigors. Dr. Dugan called to see him. It is now more difficult to arouse him. Some effort required to fix his attention and he does not recognize people well. An operation decided upon. Tumefaction of left side at neck very great, with great tenderness of apex of mastoid and along the jugular vein. I drilled into both mastoids, but found no pus. Dr. Dugan will give an account of his part of the operation.

Since the operation the patient has made an uninterrupted recovery, except a slight vertigo and deafness of left ear. No pain; no optic neuritis; vision perfect; inclined to fall to the left. The scalp wound healed readily. There was no hernia of the brain when opened. He recovered consciousness very quickly after the operation.

This case looked to me like one of pyemic thrombus of the lateral sinus. Mr. Chas. A. Ballance, of London, reports four cases of pyemic thrombi of the lateral sinus, in which he tied the internal jugular vein and curetted the sinus, with two recoveries.

DISCUSSION.

Dr. W. C. Dugan: The operation spoken of by Dr. Cheatham in his paper was done by the chisel; I used a chisel with a curved cutting edge and a mallet, instead of the trephine. I like it much better than the trephine, and you can cut down upon the lateral sinus exposing it without damage. After having exposed the lateral sinus and finding no pus with a hypodermic needle, we also explored the cerebrum and cerebellum, going very deep in the tissues, but were unable to find anything at all. If we had found in the lateral sinus a thrombus we would then have removed that, carefully dissecting out as far as the thrombus went. But finding no thrombus we stopped. I was very much surprised to find no evidence of brain trouble whatever in this case. This is the second case I have operated upon recently with the chisel, and am very much pleased with it. In regard to hemorrhage, if you should open the lateral sinus there is absolutely no danger in it. When operating on these cases we should always have a tampon of gauze ready so that when you get it open it can be tamponed at once. If proper attention is paid to asepsis during the progress of the work there will be no danger from septic trouble. You can cut down and perform an operation on the jugular using the tampon with as much success as in the lateral sinus.

Dr. A. M. Cartledge: How much brain in this case did you expose?

Dr. W. C. Dugan: A space about the size of a silver dollar.

Dr. H. H. Grant: Did you make any cut through the bone before applying the chisel?

Dr. W. C. Dugan: No. I think in craniectomy the chisel can certainly be used to good advantage. I have a patient now that I am going to operate on, and intend to use the chisel instead of the trephine. If the chisel is held at the angle of fifteen to twenty degrees there is no danger at all; no danger of doing damage to the meninges.

Dr. A. M. Cartledge: In this connection, I would state that the chisel is attracting considerable attention as a means of gaining access to the brain. I have never used it, but it does seem to me that the chisel can hardly take the place of the trephine in all cases, but it might be used to advantage in removing a section of bone between the trephine holes. I have used it in this way for years. To gain access to the brain I do not see any advantages in the chisel, and it seems to me there are disadvantages. In the first place I do not see why there is less danger of wounding the meninges. I think there is danger of injury to the dura in using the trephine and I believe there would be more danger in a slanting chisel and a mallet. The matter of sawdust is of no particular consequence as it can easily be washed away. In order to get a smooth, uniform opening, curetting is necessary by a chisel or Rongeur forceps. I have not used the chisel, as mentioned by Dr. Dugan, to take the

place of the trephine and must say I fail to see the especial advantage.

Dr. H. H. Grant: What width of chisel do you use?

Dr. W. C. Dugan: About a half inch.

Dr. A. M. Cartledge: I think that in fully one half of the cases which demand the use of the trephine, will be found one very common condition—that is, fracture of the inner table without fracture of the outer table. We all know how common it is in using the trephine to find an extensive fracture of the inner table with only a slight fracture or possibly no fracture of the outer table. I do not think there is any danger in using the trephine in these cases, but it seems to me that with the chisel there is danger of producing trauma to the brain. I do not see how the chisel can ever advantageously take the place of the trephine in such cases.

Dr. A. M. Vance: Do you think it advisable to use the trephine over the seat of fracture, or rather on one side?

Dr. A. M. Cartledge: You can never tell how much of the inner table is fractured until you cut down. Of course the trephine pin should be set on sound bone.

Dr. Wm. Vissman, (Visitor): The chisel is used altogether in Germany; they never think of using the trephine. The chisels vary in width from three-quarters down to a little over one-quarter of an inch. By using the chisel and chipping off the bone a little at a time, you can feel, in fact, you can see your way. The chisel is kept very sharp and in cases of depression, by setting it at a very acute angle as stated by Dr. Dugan, you can find this depression and, then if you should happen to slightly wound the brain, it is not going to do any great damage.

Dr. W. C. Dugan: In cases where you have a depression of the inner table the chisel should be set at a very acute angle and the bone chipped off, a little at a time, until you have entirely removed the external table, and then you have the internal table exposed. In other words you have removed the external table without coming in contact with the internal table at all. I operated a few days ago with the chisel and had excellent results. It can be used with as great a degree of delicacy as any instrument, cutting just where you wish to within a hundreth part of an inch.

STRICTURE OF THE URETHRA.

Dr. A. M. Vance: I saw a patient some time ago at LaGrange, a young man thirty-two years of age, who had stricture of the urethra and had been treated in Louisville by forcing a sound which was very large, evidently a false passage being produced, resulting in a perineal abscess which had been opened prior to my seeing him. I found an impermeable condition of the perineal stricture and a discharging sinus. I had a very short time between trains and did an external urethrotomy, of course without a guide and under great difficulties. The patient was never sufficiently under the influence of chloroform to get him in the proper position. A very large quantity of urine and pus was evacuated; the bladder was very much distended. I put in drainage and left the patient in charge of his physician. Six weeks afterward I went back to open up the anterior stricture and found it absolutely impossible to get anything through the anterior opening by the meatus. Under cocaine I worked some time with a small filiform but failed, then introduced a tenotome through the perineal opening and by this method the stricture was cut and I finally got in through the anterior urethra. The man made a very excellent recovery. One thing in the case that puzzled me very much was, after I had gotten the stricture relieved completely I could not get anything through the anterior portion of the urethra. There seemed to be a surplus of mucous membrane in the urethra that interfered with the introduction of the sound after I had put a large catheter through from behind. I never met with a case that seemed to have such a quantity of mucous membrane in the urethra.

DISCUSSION.

Dr. W. C. Dugan: I have operated several times recently without a guide with excellent success. I think if Dr. Vance had used a straight instrument instead of a curved one, he would not have had so much trouble.

Dr. A. M. Vance: At the first operation we were able to get a very fine filiform through, but could not get anything to go over it.

PELVIC DISEASE.

Dr. W. C. Dugan: I have a case that has puzzled me a great deal, and it has

also puzzled several others. The patient is a young woman upon whom a laparotomy was performed some time ago. The trouble seems to have been originally retroverted uterus. Shortly after marriage she developed considerable pelvic trouble; was under treatment for a while, and was finally operated upon and a cyst of the broad ligament removed. The ovaries and tubes at the time seemed to be in a normal condition and consequently were not removed. She does not seem to have improved very much from the operation and for the last four or five months has been growing gradually worse. Retroversion is so complete that it can be easily detected through the vagina, and she is now on the eve of another laparotomy in order to break up the adhesions and remove the tubes. She has intense pain all the time. Day before yesterday she had some rectal trouble and it occurred to me that it may be one of those reflex cases which would be promptly relieved by a simple operation. I introduced my finger into the rectum and the outlines of the uterus could be easily felt in Douglas' pouch; the ovary and tube on the left side pressed down upon the vaginal walls. I think the case is a perfectly clear one of pus tube of long standing. She has what is called "flushes," the skin becoming as red as the flush of scarlet fever; at this time her pulse is very rapid, running as high as 150 per minute and hardly perceptible, and really at times she is perfectly wild.

The tube on the left side is as large as your fore-finger. The uterus is retroverted and the tube seems to rest on the lower part of the uterus between it and the vagina.

DISCUSSION.

Dr. A. M. Cartledge: I believe that Dr. Dugan will find that while this tube and ovary are considerably enlarged it is probably the result of interference of the circulation. Operation is clearly indicated and I think the patient would be greatly benefitted.

ORIFICIAL SURGERY.

Dr. J. M. Matthews: Several years ago there was what was purported to be an anatomical discovery, as you all know, by a sect, or by some professional brothers who do not agree with our way of thinking; they discovered the so-called "pockets" or "papillæ" of the rectum. Now I would not occupy your time speaking of this matter, except that it has become a very serious one. The gentleman that pretended to have made this discovery has written a work and also gotten up a set of instruments which are used from one ocean to the other and which aid in putting the practice extensively into use. The practice is, or was, I should say, the cutting out of the so-called pockets or papillæ of the rectum; you will understand not for disease of the rectum only, but for any ailment that might affect the body. I know of one little child that was subjected to this treatment for asthma; I know of a gentleman who had his rectum, or a portion of it, excised for pthisis. I simply mention these two cases, but I could cite many others to prove how barbarous and how ridiculous the practice is. It is a surgical operation which anyone will see at a moment's glance is capably of doing a great deal of harm. For a good while they confined themselves to simply cutting out the pockets or papillæ, but now it seems they go further than this and excise a portion of the gut. Dr. Andrews, of Chicago, a very distinguished surgeon, was made aware of this fact and to him we are indebted for exposure of the treatment. He submitted the matter to a number of anatomists, among them the eminent teacher, Dr. Smith, as to whether these structures were abnormal or normal, each of whom stated that they were normal structures of the rectum, intended to assist in lubricating the feces. I submitted the same thing to anatomists of this city, Drs. Kelly, Bodine and Dugan, and each one of them agreed with Dr. Smith that they were normal structures. Therefore these men were cutting out structures natural to the parts, for any disease that a person might be suffering from, claiming that by some strange procedure they either produced the disease, or, if they did not produce it, the disease would be greatly benefitted by taking out these structures. As I say, for a time they contented themselves with the cutting out of these "pockets" and at one time I wrote an article calling the attention of the State Society to the fact that I had seen hemorrhage result, inflammation or proctitis excited, and that I had observed stricture of the gut as a sequence of such treatment. Now, they go further than formerly and resect a por-

tion of the gut, as much as an inch of the lower rectum. It is becoming so pronounced a thing that the profession of the United States are becoming aware of it, and are beginning to inquire about it. In this city the operation is being done rather extensively and, being in this line, I hear of these cases and often see them after such treatment. As I have already stated I have seen more than one stricture result from this practice. I have had several cases of ulceration of the gut resulting from the treatment. I would like to ask if the members of this society have heard anything about this wonderful (?) operation, or have met with any of the cases that have been subjected to this very unsurgical treatment. If it was not a serious matter it would be ludicrous and could scarcely be believed. I have in my possession a number of letters from physicians telling of the bad results of this practice.

DISCUSSION.

Dr. A. M. Vance: I happen to know a patient now, a young man, who consulted me on account of some trouble with his feet. Upon getting the history of the case I found he had a recent attack of gonorrhœa, and evidently was suffering from gonorrhœal rheumatism in a very aggravated form. I gave him a very blue prognosis as to the future progress of the trouble; I ordered potassium iodide and rest. This man was able to take very large doses of iodide of potassium with very little relief. He finally consulted a homeopathic surgeon who told him that his experience was that when a man was enabled to take such large doses of medicine without any effects there was some trouble with the outlets of his body, either with the urethra or rectum. He made an examination and found something wrong (?) with the rectum and excised a portion of it to cure gonorrhœal rheumatism. I have heard of a good many cases which have been operated upon by men who have been educated by the party in Chicago.

Dr. W. C. Dugan: Not many weeks ago a regular physician went from this city to Shelbyville, Ky., with the gentleman referred to by Drs. Matthews and Vance, to assist in an operation. About an inch of the lower rectum was excised and the gut brought down and stitched to the skin. I remember another patient that finally fell into my hands; the same man had treated him a long time for rheumatism, and failing to relieve him concluded there was some trouble with the alimentary canal, and performed an operation removing several pockets from his rectum.

Dr. Jas. S. Chenoweth: I can add one more case. A young lady eighteen years of age was operated upon in the manner indicated for an aggravated case of hysteria.

DOUBLE EXCISION OF THE KNEE.

Dr. A. M. Vance: I would like to mention a case I operated upon five weeks ago; a case of complete infantile paralysis of both lower extremities; a little boy nine years old, very small for his age. In the latter part of May last I excised his right knee at the Sts. Mary and Elizabeth Hospital; put the limb up in plaster of paris dressing with a spica bandage. The first dressing was removed in five weeks; when it was taken off, the wound was healed absolutely leaving a mere line without any evidence of suppuration. I will state that the operation is by a transverse incision about the lower part of the patella, removing the patella, taking off the cartilages of both the tibia and femur and putting them together without any wire or any suture, the plaster dressing serving to keep the bones in apposition. Five weeks ago I excised the second knee and dressed it in the same way; the dressings were removed yesterday and union had taken place without any trouble whatever. I will state that in the last operation no antiseptics were used, not even iodoform. I put one limb in slight flexion and the other in hyper-extension, thereby hoping that he would be able to balance himself better. I think this will give better results than if both were perfectly straight, both flexed or both in hyper-extension. This is the first time I have performed double excision of the knee where recovery has taken place.

Something Might be Made of It.

A correspondent of the *Confectioners' Journal* says that banana-juice makes a first class indelible ink. A spot on a white shirt from a dead ripe banana is marked forever, and the juice of bananas thoroughly decayed is a bright, clear carmine.

CORRESPONDENCE.

NEW YORK LETTER.*

New York surgeons are beginning to use the microscope extensively in order to ascertain how much and what adjoining tissue to remove when excising a malignant growth. The surgeon has a competent microscopist at hand, and as soon as he makes the first incision, a particle is removed, a frozen section made and examined. Should the operation be upon the breast, and carcinoma cells found in this section, the axillary glands are removed whether they be involved or not. Portions of tissue are removed at variable distances from the seat of the growth and examined, and this process is kept up until healthy tissue is reached; a section can be prepared and examined in ten minutes.

Stiles, of Edinburgh, has proposed a method of ascertaining the extent of involved tissue which gives good results. He takes a piece of suspected tissue and after washing, places it in a five per cent solution of nitric acid for ten minutes. The acid changes the normal tissue so that it appears semi-translucent while the diseased portions remain opaque. These methods of testing can be carried on while the operator is removing the main growth, so that before the closure of the wound he can remove all the parts found to be involved.

***

Resorcin is rapidly gaining popularity in the treatment of chronic gastritis. Prof. W. H. Thomson has recently reported the results of its trial in a series of seventy-eight cases taken from private practice; all of these cases presented pronounced gastric disorder. In fifty-one of these cases the drug yielded brilliant results. The cases of gastritis which it failed to relieve were due to a true organic derangement or to a neurotic element, such as hysteria, epilepsy, or insanity; in cases where the neurotic element was subsequent to and dependent upon the gastric trouble there was marked beneficial effect. In seventeen of the cases which were treated successfully there were symptoms of gastric ulcer, pain and vomiting.

In cases of what the professor terms railroad dyspepsia,—a gastritis found in men who do business in the city and live in the country, who eat breakfast and lunch with watch in hand, swallowing half masticated food, and riding to and from their homes in a smoking car—resorcin was found to give brilliant results.

It has been found also that while resorcin will not relieve a present attack of sick headache, it will prevent a subsequent one. In cases with an hereditary tendency to migraine the symptoms ceased as soon as an existing gastric trouble was relieved by the use of resorcin.

The drug comes to us in the form of a white, crystalline powder; soluble in ether, alcohol, oil and water, but not in chloroform. The dose is five grains, given well diluted, three times a day, half an hour after each meal.

***

A certain popular Jersey dairy has for some time been suspected of yielding tuberculous milk. The cows were of a high grade and because of the richness of the milk, it was sold only to wealthy New York families and at a high price. A couple of months ago one of the city health officers tested twenty-five specimens of milk from as many of the cows and in twelve of the specimens found tubercle bacilli. The animals were sentenced to death; to which proceeding the owner very naturally objected, and the milk continued to be sold.

About a month ago several cans of the milk were seized and specimens sent to Carnegie Laboratory for examination. A portion of one of the specimens was, under aseptic precautions, injected into a healthy guinea-pig, the family history of which showed no tuberculous taint, the animal itself and several generations of its ancestors having been reared in the laboratory.

Soon after its inoculation the guinea-pig became emaciated, gradually grew weaker and in two weeks died. The autopsy showed that the mesenteric and inguinal glands were enlarged and had cheesy centers, while in the liver and spleen were

*Special Correspondent to THE MEDICAL AND SURGICAL REPORTER.

numerous miliary tubercles, the centers of which had undergone cheesy degeneration. Sections were prepared from the spleen and liver and examined microscopically and tubercle bacilli found. The healthy lungs showed that the animal was not tuberculous previous to its inoculation. The diagnosis of death from acute miliary tuberculosis was made, and the Jersey dairy condemned.

NEW YORK STATE MEDICAL SOCIETY.*

ALBANY, Feb. 7th, 1893.

Dr. L. C. Gray, of New York, read a paper upon "The Relation of Genital Irritation, in the Male and Female, to Nervous and Mental Diseases."

A careful review of the history of genital irritation was first given, dating back to the belief of Hippocrates (which has been the source of the modern doctrines upon the subject) and this was followed by a discussion, in some detail, of the literature which sprang up after the publication of Stanley's paper, in 1833, as well as the further revival of the question by Sayre, in 1870.

Dr. Gray then went on to say that there was no proof that genital irritation was capable of causing any of the organic diseases of the nervous system, but that it might possibly act as an exciting or aggravating factor of certain lesser nervous diseases. In mental diseases, however, relief of genital irritation has proved, in his opinion, to be a much more valuable method of treatment than it seemed to be in the lesser nervous affections. He called attention, however, to the fact that there were two great classes of mental diseases—namely, the organic insanities and those which are known as the psychoneuroses—and that, so far as was yet known, it was only in the latter that relief of the genital irritation was of any value. He then gave the histories of several cases of insanity in which operations upon the female genitalia had given prompt and permanent relief. He was not, however, willing to believe that all the relief was due to the removal of the genital irritation, because simple etherization had sometimes worked almost as well, and, in one case, had done quite as much as the operation itself would have affected. He furthermore called attention to the fact that, if the operation upon the female genitalia was of any value at all in the relief of mental disease, it should only be done at a proper stage of convalescence. His conclusions were as follows:

1st. That there is no proof that genital irritation, in the male or female, can cause nervous or mental disease, except in the predisposed individual.

2nd. That the proof is not yet absolute that genital irritation can produce nervous or mental disease, even in the predisposed individual.

3rd. That there is undoubted proof that relief of genital disease, in the male or female, will often relieve certain nervous diseases, such as migraine, hysteria, epilepsy, simple nervousness and hallucinatory insanity.

The Cold Bed.

If trustworthy statistics could be had of the number of person who die every year, or become permanently diseased from sleeping in damp or cold beds, they would probably be astonishing and appalling. It is a peril that besets traveling men, and if they are wise they will invariably insist on having their beds aired and dried, even at the risk of causing much trouble to their landlords. But, according to *Good Housekeeping,* it is a peril that resides also in the home, and the cold "spare room" has slain its thousands of hapless guests, and will go on with slaughter till people learn wisdom. Not only the guest, but the family often suffer the penalty of sleeping in cold rooms and chilling their bodies at a time when they need all their bodily heat, by getting between cold sheets. Even in summer a cold, damp bed will get in its deadly work. It is needless peril, and the neglect to provide dry rooms and beds has in it the elements of murder and suicide.—*Amer. Anal.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, FEBRUARY 11TH, 1893.

EDITORIAL.

THE EXAMINATION OF SPUTUM FOR TUBERCLE BACILLI.

The most practical use that has thus far been made of the discovery of the tubercle bacillus is, undoubtedly, its value in the diagnosis of pulmonary tuberculosis. The satisfactory results in the treatment of this disease that are constantly being reported, when the patients are placed under proper conditions in the beginning of the invasion of the bacilli, emphasize the importance of a correct and *early* diagnosis. It is well known that when the changes in the lung tissue have advanced to a sufficient extent to admit of a differentiation by physical signs or symptoms there is little hope of an ultimate recovery. The difficulty that has heretofore existed in recognizing tuberculosis in its incipient stage has compelled many a physician to allow his patients to pass beyond the reach of medical aid before the real nature of their disease was determined and an opportunity given then to test the virtue of a better climate or other curative agents which are proving so beneficial when applied at the proper time. It is to avoid this error that physicians should avail themselves of all the assistance that scientific research has developed for them.

The fact has been amply demonstrated that tubercle bacilli can be found, in most cases at least, in the sputum of patients suffering from pulmonary tuberculosis long before the nature of the disease would otherwise be suspected. As bronchitis is frequently the apparent means of preparing the lungs for this invasion of the tubercle bacilli it is self-evident that, in all cases of lung or bronchial disturbances that do not yield promptly to the usual treatment, the sputum should be examined in order to detect the bacilli at the earliest possible date if they should be present. It is in such cases only that the discovery of tubercle bacilli in the sputum is of practical or beneficial value.

To a few this may appear as an unnecessary precaution but the time has come in the building up of a better, more thorough and scientific system of medicine when a failure to diagnose the disease

in question (in the great proportion of cases at least,) at a time when restoration can with reason be expected, may be considered as little less than an unpardonable offence.

The examination of sputum by means of the methods set forth by Koch, Ehlrich and others required so much time that their application was quite beyond the possibility of the busy practitioner. The methods, however, have, within the last few years, been so much improved and simplified that it is hoped they may be employed whenever the discovery of tubercle bacilli will clear up a doubt in the diagnosis.

From among a large number of methods that have been published the one recommended by Dr. Gabbett appears to us the most practicable especially for sputum examination.

The sputum (the first expectorated in the morning is preferable) is spread in a very thin layer over the surface of a cover-glass and allowed to dry in the air. The cover-glass preparation (as it is now called) is passed, film upwards, three times through the flame of a spirit lamp or a Bunsen burner, in order to fix the film on the cover-glass so that it will not be lost during the subsequent treatment. It is then covered with a few drops of the staining fluid (which consists of Fuchsin 1 gram; Absolute Alcohol 10 cubic centimeters; 5 per cent. Carbolic Acid 100 cubic centimeters). The stain is allowed to act for about two minutes. The preparation is then rinsed in water and the film again covered with the decolorizing and counter-stain solution (Methylin blue 2 grains; 25 per cent. Sulphuric Acid 100 cubic centimeters) which is allowed to act from one to two minutes when it is again rinsed in water. It can be mounted in water and examined at once, or allowed to dry when it can be permanently mounted in balsam.

The tubercle bacilli should appear upon a microscopical examination as slender, more or less curved, rod-shaped bodies of a deep red color, the surrounding tissue cells and other bacteria having a blue color. For these solutions care must be taken to secure pure Fuchsin and Methyline-blue.

In the beginning of the invasion of the bacilli it is often impossible to detect their presence in cover-glass preparations made from a single specimen of sputum. As a large number of negative results do not positively affirm the absence of the disease, several specimens should be examined.

Biedert, (*Berl. Klin. Wochenschrift, 1886,* No. 42, p. 43, ibid 1891, No. 2, p. 31) has recommended a very excellent method for detecting the bacilli when they are present in very small numbers, which in the hands of a careful workman is much simpler than the repeated examination of cover-glass preparations made directly from the sputum. The method consists in mixing a considerable quantity of sputum with twice its volume of a 2 per cent. solution of caustic soda and boiling the mixture until it is perfectly fluid, after which it is placed in a conical dish and allowed to stand until a sediment is formed. The soda solution dissolves the tissue cells leaving the bacteria and elastic fibres, if any are present, to form deposits in the bottom of the glass. Upon decanting the supernatant liquid tubercle bacilli, otherwise difficult or impossible to find, can readily be discovered in properly stained cover-glass preparations made from the sediment. Although this process requires considerable time the advantages to be gained are obvious, and the importance of an early diagnosis over-balances the time and care that any of the methods require to detect the presence of the invading bacteria.

Perforation of the bowels occurs in about eight per cent. of the cases in typhoid fever.

TRANSLATIONS.

A CASE OF HYPERTROPHIED FLOATING SPLEEN; SPLINECTOMY WITH RECOVERY—A. C. LINDFORS.*

The case, that of a peasant of 20 years, was admitted into the hospital the 18th of January, 1892. Examination of the abdomen showed a large, solid, smooth tumor in the left side and was diagnosed as the spleen; it was remarkably movable, falling to the right of the abdomen as the patient changed her position to that side; its lower portion extended almost into the pelvic cavity, while the upper was broad and disappeared under the border of the left ribs. The length of the tumor was 29 cm., the breadth 17 cm., the girth, at the umbilical region, 95 cm. The patient complained of great pain in the abdomen, had noticed an increase in her size for five years. She was anemic, emaciated, had always been weak. Heart and kidneys healthy, some slight pulmonary catarrh from a former attack of influenza. Examination of the blood revealed one white blood corpuscle to 250 of the red.

She was desirous to have an operation performed. The author at first declined and tried the administration of tonics—quinine, arsenic and iron. No improvement following, laparo-splenectomy was performed on the 21st of February. Chloroform was used first to produce narcosis after which ether was substituted. Duration of the operation was two hours. An angular incision was made, its vertical portion corresponding to the external border of the left rectus—abdominis muscle, measuring from the umbilicus upwards 18 cm. The horizontal portion, at the upper extremity of the vertical and extending towards the left, measured 6 cm. There were some adhesions between the omentum and the tumor; these were ligated and severed. The entire spleen could be easily drawn out through this opening, the intestines being controlled by compresses.

Ligation of the ligamenta gastro and phrenico-linealia was done with silk in six sections, inclosing both end ligatures. There was but one row of ligatures. The tumor was grasped above by large compression forceps to prevent much hemorrhage, and then severed with the scissors; there was very little bleeding. The arteria and vena linealis were ligated with cat-gut. A small accessory spleen, about the size of an almond, was also extirpated; the stump was dropped; the abdominal wound sutured with two rows of sutures, the inner of cat-gut uniting the peritoneum, the outer of silk uniting the fascia muscle and skin. No shock, the patient retracted well; no fever during the first few days, later some febrile reaction with increase of pulse rate and pain in the left hypochondrium.

Removal of the suture on the 8th and 10th day; union by first intention; a diffuse resistance in the left side by palpation. On the night of the 8th of March and on the following day, the patient had several movements, blackish in color, mixed with pus, after which the temperature and pulse became normal. Complete and uninterrupted recovery followed. On the 18th of March examination of the blood showed the relation of one white corpuscle to 150 of the red. The quantity of hæmoglobin was 55° (Fleischl's Hämometer) in comparison to the 90 or 95° found in healthy women. With Hedin's Hæmatokrit the red blood corpuscles were found to be 32 per cent. in comparison to 42 per cent., and the white three to four per cent against the one. This shows a diminution in the quantity of hæmoglobin and the number of red blood corpuscles while there is an increase of the white. The spleen weighed 1155 grm., the blood included. It measured 25 cm.x15 cm.x7 cm. On the 14th of April the patient went home, very much improved. Was seen again on the 6th of June, when she reported that she was well, could work and had no more pains. The lymphatic glands around the thymus (?) were enlarged. This is the first case in Scandanavia of successful extirpation of the spleen. *Nord. Med. Archiv.* 1892.

Gangrene of the Hand Consecutive to Influenza.†

M. Roland has published in *La Rev. Me'd. de la Franche-Comte*, an interesting observation of gangrene of the hand due to an endarteritis consequent upon la grippe, which was followed by death. The patient was a smith 31 years of age, very robust, without antecedent trouble of any sort, who had a grave attack of influenza. Scarcely recovered, he resumed his profession, and performed excessive work with his right hand. Following this fatigue he was attached with lively pains which were at first taken for rheumatism. Finally, however, the hand became white, livid; the pulsations of the radial and even of the brachial at the fold of the elbow disappeared; finally, the fingers and the lower half of the hand assumed the black coloration of gangrene of arterial origin, which is often seen in the lower extremities, but which is quite exceptional in the upper extemities.

In the course of time a line of demarcation formed between the dead and living tissues, and the patient seemed about to recover when his general state became grave, the right foot became involved in its turn, and death followed.

Gangrene consecutive to influenza has already been noted, but these gangrenes, due generally to an arterial embolus have never been noticed in the hand. It is on this ground that M. Roland's case merits reporting.—*Le. Bulletin Medical*, Jan. 8, 1893.

Some Remarks on the Treatment of Pain and Insomnia.†

According to Dourdoufi, pain and insomnia are morbid phenomena of much importance especially from the point of view of their practical signification. They exist in the clinical picture of a large number of diseases both acute and chronic. In the chronic diseases the issue of the pathological process depends largely upon the intensity of these symptoms and the possibility of limiting their deleterious influence. A rational medication of pain and insomnia, based upon the recognition of their pathogeny facilitates the rôle of the physician in his struggle with the diseases. Dourdoufi calls attention to a simple method of treating pain in general and cephalgia especially.

1. In the case of cephalgia, if it does not depend upon organic lesions of the nervous system, we have in *percussion with the fingers or with the finger* upon the parts which are the seat of the pain a simple and sure method of causing the pain to disappear almost immediately. In the examination of a patient who complained of atrocious pain in the head, Dourdoufi practiced percussion of the skull with the finger for the purpose of clearing up the nature of the cephalgia. This examination was followed in two or three minutes by an entire disappearance of the cephalgia. The experiment was repeated in a number of instances and always with the same positive result. The percussion may be made with one or several fingers, taking the precaution not to occasion disagreeable sensations to the patient. This may be accomplished by controlling the intensity of the percussion according to the sensitiveness of the patient, and gradually increasing the force of the blows. As a general rule the percussion should never be too intense. This method ameliorates and even causes an entire disappearance of every form of headache of a functual nature, without organic lesion; hemicrania, and headaches of neurasthenic, hysterical and anemic patients.

The same method has been applied to the muscular pains of neurasthenics with the same positive result. Percussion with the fingers for three to five minutes has caused the muscular pains to disappear in cases where the application of electricity (galvanization and franklinization) and massage have remained ineffectual.

2. Dourdoufi has also obtained very satisfactory results in the treatment of *rebellious insomnia* by another therapeutic method. A young man thirty years of age who had been tortured for several months by an insomnia for which sulphonal (2 grammes) and chloral (2-3 grammes) had been used without effect, applied to him. He advised his patient to take, after retiring, some cold milk (previously boiled,) three teacupfuls, and if possible more. This was taken every evening during the first hour and a half after retiring, the amount varying from three to six cupfuls. The result was very good, a calm sleep following, which lasted on an average eight hours. It is worth while to note that this result was obtained in an individual in whom sulphonal and chloral had not produced the slightest somnolence.—*Le Med. Mod.* Jan. 7, 1893.

† Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

Contributions to the Diagnosis of Cancer of the Pancreas by Drs. E. Galvagni and G. Bassi.*

Cancer of the pancreas is always difficult of diagnosis, although it is known to occur more often than was formerly supposed. The text-books give very little enlightenment on this subject. Galvagni and Bassi had an opportunity of observing four cases of cancer of the pancreas during life and after death. They present the result of their studies to the profession. This disease may or may not be accompanied by jaundice, which when present is differentiated from the ordinary icterus by the presence of diarrhœa and sub-normal temperature. Its onset is usually sudden, its course progressive with no remission. The gall bladder is enormously dilated, but the liver is not enlarged. In consideration of the short duration of the disease the diagnosis in the presence of jaundice will not be so difficult. On the other hand in those cases in which jaundice is absent diagnosis can be made only by exclusion; it being necessary to exclude cancer of the liver or stomach. Jaundice occurs in about 75 per cent. as one of the first symptoms of cancer of the pancreas, and particularly when it locates itself near the head of the organ. Pain and vomiting are not a constant symptom. In most cases there is no loss of appetite and dyspeptic symptoms are absent. Palpation reveals, in about two-thirds of the cases, a small tumor in the right epigastric region between the liver and umbilicus, not always sharply defined. The most important and constant symptom is the emaciation which takes place with remarkable rapidity.—(*Rivista clin. e terapeut.* No. 11, 1891.)

A Case of Echinococcos in the Throat.*

P. Güterbock reports a case of a patient nineteen years old, who presented about the middle of April, '92, a swelling in the left lower angle of the jaw which was reddened and immovable. Thinking it to be a suppurating gland Güterbock made an incision and discovered a echinococcos cyst which extended into the substance of the sterno-cleido mastoid muscle: extirpation—good recovery. He has looked up the literature of this subject and found twenty-six cases reported, nine of which were located in the thyroid gland. They are usually met with in young people, more often in females and the left side is the one usually attacked. It is easily mistaken for an abscess. The symptoms of these twenty-six cases have been mostly negative.

E. von Bergmann has called attention, as characteristics of this affection, to its rapid growth and its location, *i. e.*, the external border of the sterno-cleido mastoid muscle. Therapeutically little is known of three of the twenty-six cases. The exploratory incision has been rarely used; when decided upon it usually ended in complete extirpation. The incision was made in fourteen cases, ten recovered, three died of hemorrhage and the result of one case is unknown.

The text-books usually teach that it is dangerous to extirpate the capsule of the echinococcos owing to its intimate connection with surrounding tissues and advise leaving it *in situ*. This, however, has given rise to many complications in the course of recovery.

In six cases, in which the operation was completed by thorough extirpation of the capsule, rapid and complete recovery took place. In four cases puncture was resorted to with injection and drainage. Among the twenty-four operated cases there were eighteen recoveries, three deaths, and in three the results were not known.—(*Deut. Med. Zeit.*, No. 6, 1893.)

Trional as a Hypnotic.*

Boettiger has used trional in many nervous cases, also among the insane, and found that it is a remedy which possesses decided hypnotic and quieting properties while it does not leave any unpleasant effects after its use if given, in moderate doses (the maximum 3 g.) Sleep usually sets in rapidly (fifteen minutes.) In uncomplicated cases of insomnia one grain, or the most two, is usually all that is necessary. In cases of great irritation small doses given during the day will often produce the desired effect. It does not act as an anodyne. It is ineffectual in cases of alcoholic delirium.—(*Ber. Klin. Wochen*, XXIX., 42, 1892.

A Case of Tuberculosis of the Intestines Accompanied With Black Urine.*

Dr. Pollak, of Budapest, reports a case: A child of ten years, from healthy family, was taken ill in Jan. 1891, with pain in the abdomen and profuse diarrhœa which lasted three and a half months. There was also present fever and slight cough. The patient became anemic and emaciated, and the urine throughout this illness was always dark colored. The abdominal cavity seemed to contain fluid, and the lower extremities were œdematous; temperature normal. The urine presented strange characteristics; when freshly voided it was usually clear, of a yellowish brown and sometimes dark brown color; if exposed to the air for a time it became darker, the upper portion turning black after twenty-four honrs and becoming more dense as a longer time elapsed. The amount voided during the twenty-four hours ranged between 100 to 300 ccm. The specific gravity was 1,008 to 1,030; the reaction was usually alkaline, rarely acid; neither albumen, pus, blood, biliary coloring matter, sugar or asceton could be found. Indican was always present in large quantities if examined in the fresh state, or after longer standing urobilin was only present in traces. The patient rapidly sank and died and the section revealed numerous chronic tubercular abscesses along the entire ileum, and the entire peritoneum was studded with tubercles. No melanotic swelling could be found. This condition of the urine is rarely met with, especially in the absence of melanotic tumors. It has never been met with in tuberculosis of the intestines, but has been observed by Senator in tubercular diseases of the other organs, notably a case of tuberculosis of the lungs and one of the peritoneum.—(*Deut. Med. Zeit.*, *No.* 6, 1893.)

The Use of Anæsthetics in Obstetrics.*

Dührssen speaks of the value of narcosis in obstetrical operations and states that it can be used without the aid of another physician. His method is to chloroform the patient deeply after which the operator proceeds with the operation in hand, allowing only occasionally about two drops of chloroform when the patient reacts.

Aside from the relief produced by narcosis in painful labor, it often aids very materially in making a correct diagnosis; for instance, it is sometimes difficult to decide between a transverse and a posterior parietal presentation. Its principal use, however, is found in cases of version or in the removal of adherent placentæ after abortions, the removal of tumors in the lower pelvis or breach presentation when it becomes necessary to deliver by the feet.

Dührssen, however, recommends care in septic cases and considers it contra-indicated in eclampsia for the purpose of controlling the attacks. It should only be used in these cases, to aid prompt delivery and should be deep and thorough for that purpose.—*Ber. Klin. Wochen*, '92.

Contributions to the Surgical Treatment of Stenosis of the Pylorus.*

F. Colzi presents three new cases of pyloroplasty performed after the method of Heineke–Mikulicz; all recovered. The stenosis was produced in the first case by an abscess. The second followed what the author believes to have been a gastropyloritis hyperplastica. Clinically it appears to have had about the same symptoms as the stenosis produced by carcinoma. The third, followed the caustic action of sulphuric acid taken by accident.

The author further reports a case of pyloric stenosis produced by adhesions between the pylorus and the liver which followed an attack of pericholecystitis. The operation consisted in releasing the adhesions and was followed by complete recovery.

A gastro-enterostomy for carcinoma of the pylorus. The patient died on the fourth day owing to persistent vomiting of biliary matter.

A section proved that the vomiting was induced by a contraction of the proximal loop of the intestine, behind which larger masses of fluid matter collected, which by over-distention would partially overcome the stricture and entering the stomach at once induced vomiting.

The only method by which such a complication could be overcome seemed to the author's mind to be an additional operation of entero-anastomosis.—*Central. f. Chir.*, No. 50.

ABSTRACTS.

THE RELATION OF PELVIC DISEASE AND PSYCHICAL DISTURBANCES IN WOMEN.

Dr. George H. Rohé, Superintendent of the Maryland Hospital for the Insane:

The opening remark of this most interesting article is worthy of profound thought: "Physiology as well as daily observation teaches the interdependence of mental and bodily functions," and while he states that, "the brain is the organ through which the phenomena of mental action is displayed and must necessarily be the immediate seat of disturbances of nutrition as causative of disorders of function, there can be little doubt that in many cases some more remote cause is present in the physical organism, to which the disturbances in the brain function are traceable.

The depressing effect of disorders of digestion and entire gastro-intestinal tract upon the mental state, he proves by his own observations and the experience of other authors and alludes to Clouston "who made the observation that delusions of intestinal obstruction so frequent in melancholia may after all be dependent upon some physical condition hindering the passage of the contents of the gastro-intestinal canal; in other words they may not be delusions at all." A recent autopsy in the Maryland Hospital for the Insane showed the truth of this observation. The case was one of profounded hypochondriacal melancholia, which had before admission been diagnosticated as cancer of the stomach, had required feeding for his entire period of residence (three years); there was constant complaint of obstruction of the bowels, although no abnormality could be made out on physical examination. After death the descending colon was found constricted for a distance of six inches to a diameter of not over half an inch."

The author furthermore calls attention to the fact that, "The mental disturbances—actual insanity, not merely febrile delirium—accompanying or following infectious maladies, structural or nutritional diseases of the eye, ear, heart, lungs and kidneys are generally recognized. Indeed some of the highest authorities on mental diseases, as Esquirol and Guislain emphasize the overwhelming influence of the genital organs, especially in women, in the production of insanity. Strangely, however, while physiologists recognize and impress the great influence of the normal sexual function upon the mental state of the individual, alienists, generally, seem disposed to deny any influence to these organs when in a morbid condition. The fact cannot be denied that at the menstrual period all psychical disturbances are intensified. Maniacs become more noisy and disturbed, epileptics have more frequent and more violent attacks, and melancholiacs are more disposed to depression and suicide at that time. The author, knowing by observation the above to be true, finds it very irrational that the influence of abnormal conditions of the genital organs upon psychical processes should be so vehemently denied. He quotes from Tuke who says that, "insanity is not a disease. It is a symptom produced by many morbid conditions which may arise primarily in the brain, or secondarily, from depraved conditions of the general system." Indeed this same authority utters this strong reproach to the alienists. "No one will venture to say that the foundations of general and so-called psychiatric medicine are equally firm or established on similar principles. No, the general conception of insanity is on the same level as that of dropsy a century ago; and its varieties — mania, melancholia and dementia—are not one whit more pathalogically definite than the anasarca, ascites and hydrothorax of that period, and they must remain so till such time as the subject is studied by the same lights as those which enabled the anatomist and pathologist to break up the generic term dropsy into a series of widely different conditions possessing a common symptom.

Following out this line of thought and reasoning, and stimulated by a few others who have written upon and discussed the subject, Dr. Rohé began to work out this humanitarian problem, his position no

doubt giving him the opportunity of making a careful selection, backed up by a thorough knowledge of former history and habits of each patient.

We can do no better than to quote his own words, regarding his opinion of gynecological treatment, while we heartily endorse them. "There can be little doubt that the frequent exposure of the patient and introduction of the speculum, the passage of a sound and attempted forcible reposition of a retroverted and adherent uterus, the introduction of a pessary, or perhaps, worst of all, the practice of that form of vicarious masturbation, known as pelvic massage, would lead to results the reverse of beneficial in the insane, as they have resulted in sane women.

Modern surgery and gynecology, however, offer and produce positive results, principal of which is the relief of suffering."

The author then explains in detail the care and preparation of each patient previous to examination, *i. e.* baths, free purgation and douches—and in order to make the examinatian thorough and satisfactory an anæsthetic was employed. Imbeciles and dements were not examined though he feels confident that he would even here meet with a large proportion suffering from pelvic disease. Of the 35 examined, 26 or 74.3 per cent showed some evidence of pelvic disease or abnormality.

In fact Dr. Rohe feels confident that at least 50 per cent. of the women in the Maryland Hospital for the Insane would show lesions of the genital organs if all were thoroughly examined. In some unexamined cases an autopsy had shown unsuspected pelvic disease. Should not this be an incentive to the heads of other institutions to make similar investigations. The total number of cases operated upon was 18, six of which were suffering from melancholia, one of simple mania, four of puerperal mania, one hysterical mania, two periodic mania, one hystero-epilepsy with mania, and three epilepsy.

Of the 6 cases of melancholia the doctor reports all have recovered from the operation and some improvement can be seen in their mental condition. Of the case of simple mania, he states that there seems to be decided connection between the uterine displacement and the mental aberration. The patient since the operation has shown decided improvement in her mental condition, although not well enough to be discharged from the hospital.

Of the four puerperal mania, he reports that in all there were lesions of the pelvic viscera sufficient to demand the operation. The operations were followed by prompt and complete recovery and the conclusions, which the author has arrived at in this connection we take pleasure in quoting.

1. Puerperal insanity is, in at least the large majority of cases, an infection psychosis. 2. Without rejecting the influence of other factors, such as heredity anemia, exhaustion, mental shock, and distress, careful observation will show that few cases of puerperal insanity occur without preceding or coincident puerperal infection.

The reasons for this opinion may be briefly summed up as follows:

1. Puerperal insanity occurs in the great majority of cases within the first ten days, after delivery, about one-half in the first five days—the same period during which puerperal infection usually occurs.

2. It is usually accompanied by elevation of temperature and other evidences of febrile disturbances.

3. The clinical form in which puerperal insanity manifests itself is, in the majority of cases, that of acute, delirious or confessional mania. Depressive states are rare except as secondary form. In other words, the most frequent condition is one most closely resembling febrile delirium.

4. The death rate is much higher than in simple mania. Death occurs from exhaustion, usually with high temperature and rapid pulse.

5. Post mortem examinations, though apparently infrequent in these cases, have shown grave involvement of the pelvic viscera.

6. Examinations of the pelvic organs during life show lacerations of the perineum and cervix uteri (facile channels of infection in the puerperal woman.) As secondary conditions are found intrapelvic (peritoneal) inflammations, and consequent abnormal locations, fixations, and congestions of the uterus, tubes, and ovaries.

7. The results of operations seem to show that removal of local sources of irritation increases the chance of recovery from the mental disease."

To sustain those propositions he quotes from Tuke's "Dictionary of Psychologi-

cal Medicine." "There is strong reason for believing that in purperal insanity a considerable proportion of cases is due to toxic influences.

It must be remembered that although a woman may become insane during the puerperal period, her case need not be referable primarily to child-birth. Mental symptoms may be, in point of fact, idiopathic—*i e.*, the result of so called normal causes—the effect of which, culminating at the birth of her child, show themselves some three weeks or a month later by an attack of simple mania or melancholia. But the violent delirious mania which is apt to develop within fifteen days after delivery has all the aspect of being due to toxic influence. Its sudden inception, delirious character, rapid development, inflammatory complications, and tendency to death are eminently suggestive of septic origin. Such cases rarely present themselves later than a fortnight after childbirth (the period during which septic changes go on in the uterus,) and more frequently within ten days. Absorption from the uterine surface of disorganized material and blood, acting on a system which has been already subject to considerable drain, exercises its influence on the most highly organized cells, and acute, violent mania, temporary in character, but followed by prolonged brain weakness, is the result."

After giving each case operated upon in detail in which with very few exceptions changes for mental improvement have been noticed, the author gives the following conclusions. "In the first place, I believe the facts recorded demonstrate that there is a fruitful field for gynecological work among insane women."

Secondly, that this work is as practicable and can be persued with as much success in an insane hospital as elsewhere.

Thirdly, that the results obtained not only encourage us to continue, but require us in the name of science and humanity to give to an insane woman the chance ot relief from diseases of the ovaries and uterus that a sane woman has." —*Abstracted from the 95th Annual Report of the Maryland Hospital for the Insane.*

THE LIBRARY TABLE.

Text-Book of Ophthalmology. By Dr. Ernest Fuchs, Professor of Ophthalmology, University of Vienna. Authorized translation from the second enlarged and improved German edition, by A. Duane, M. D., Assist. Surg., New York Opthalmic and Aural Institute. With numerous illustrations. New York: D. Appleton Company, 1892.

So many new works upon Ophthalmology have recently been issued that there would seem scarcely room for another. But when we carefully peruse the book before us it becomes evident that many of the remarks and illustrations contained in it, have been reproduced in some of the other recently published works. This must certainly be taken as direct testimony to the value and appreciation of Prof. Fuchs's work, which may be characterized as comprehensive, scientific and authoritative. It is divided into four parts, with an appendix. The first part describes the methods of testing the eye. The second, containing fifteen chapters, treats of the various diseases of the eye and its muscles, the eyelids and the orbit. Part three discusses anomalies of refraction and accommodation. Part four is devoted to operations. The appendix which is added by the translator contains wood cuts of instruments.

The chapter upon the Ophthalmoscope would have been more complete if graphic representations had been given of the surgeon in the act of examining a patient by means of the direct and indirect methods, as well as an illustration of examing by focal illumination; and the wood cut of the normal fundus oculi on page 9 represents the optic papilla as oval longitudinally, simulating the ophthalmoscopic appearance of the optic disc in an astigmatic eye.

Each chapter on diseases of the eye begins with a description of the anatomy and physiology of the structure under consideration. To some readers this arrangement may be more serviceable than would be an introductory complete description of the anatomy and physiology of the eye and its appendages although to us, the latter plan seems preferable. The various diseases of the eye and their treatments, are very clearly and thoroughly described, and the chapters on disease of the iris and ciliary body, glaucoma and cataract are especially worthy of mention. Professor Fuchs speaks with no uncertain sound as to iridectomy performed as early as possible as the treatment *par excellence* of glaucoma. He emphasizes his view with the authority born of experience. In this section some etymological changes in words are noticeable. For instance, the word generally, but erroneously, spelled *choroid* is printed chorioid (page 245), again *myosis* is written *miosis*, (page 257.)

The chapters on anomalies of refraction and accommodation, the disturbances of mobility of the eye and their correction, present nothing for special comment save that it is

refreshing to find here, as well as in other parts of the work, due credit accorded to the labors of the masters of modern ophthalmology, Donders, Von Græfe, Arlt, etc.,—references to whom are very sparingly made in recent American works upon the subject.

A great deal of historical information is scattered throughout this work and adds much to the interest in reading it.

The operations upon the eye are very faithfully described and, in the appendix, illustrations of the various instruments required are shown. More representations of the *methods* of using them would, we think, have added greatly to the usefulness of the work.

As the shadow test (Retinoscopy) is now being so generally studied it is disappointing to find the description of it so incomplete, and noticeably there is no reference to the use of the plane mirror. Credit is due to the translator for the manner in which he has presented Professor Fuchs' work to the English speaking public.

Handbook of Massage. By Dr. Emil Kleen, Practicing Physician in Carlsbad, Bohemia. Authorized Translation from the Swedish, by Edward M. Hartwell, M. D., Ph. D. Philadelphia: P. Blakiston, Son & Co., 1892.

A favorable impression of Kleen's Massage is formed the instant that the *Introduction to the American Edition* is read, for it is written by Dr. S. Weir Mitchell, who is a reliable observer and a champion of Massage.

This book will meet with a ready acceptance since, as Dr. Mitchell has said, "We needed a study of this theraputic aid from a higher point of view than that of the mere masseur, who is too apt to see in massage an agent applicable to all diseases. Those who have wearily retired from the mystery, or excessive detail or too positive conclusions with which the professional masseur, when writing of massage, surrounds and complicates a simple matter, will I am sure, be pleased to find it considered without excess and with clear, good sense." Those who desire to learn what is at present known of massage, its uses, methods and effects, can find here what they are not likely to get in any other work on this subject.

Kleen's book, will be of great value to the practicing physician, for it is free from all specialistic narrowness and enthusiasm for massage; does not run into extravagance in setting up indications for its use, but assigns to it a place among other adjuvant measures of therapy.

Dr. Hartwell has done his work in an excellent manner. He has used rare discrimination in his introduction of illustrations. The presswork, paper and binding are commendable.

Fermentation, Infection and Immunity. A new theory of these Processes, which Unifies their Primary Causation and Places the Explanation of their Phenomena in Chemistry, Biology, and the Dynamics of Molecular Physics. By J. W. McLaughlin, M. D., Austin, Texas. Austin, Texas: Eugene Von Bœckmann, Publisher, 1892.

This subject which had its birth in an article on "The Etiology of Acute Infectious Diseases" which appeared in the *Texas Med. Journal* 1887, reappeared in 1890 before the Texas State Medical Association in a new dress, "An Explanation of the Phenomena of Immunity and Biological Laws." But the paper the author states was seriously crippled by its brevity, and he found it impossible to intelligibly and fully include a subject so complex and novel within the compass of a society essay. Hence its appearance in book form. The aim and purpose of the author is to show that the accepted principles of molecular physics, and those of chemistry and biology, if supplemented by legitimate deductions from them, are amply sufficient to account for all the known phenomena of these processes, and also, to explain their relationship and intimate nature. The theory is as new as it is novel and the future will decide as to its accuracy.

Deutches Archiv fur Klinische Medicin. Edited by Dr. H. V. Ziemssen and F. A. V. Zenker. Band 50, containing 530 pages with 2 portraits, 13 tables and 14 plates. Published by F. C. W. Vogel, Leipsig; December 1892.

The Archiv, comprising as it does, over twenty-six essays upon important subjects by prominent authors, will bear with profit close study in detail.

The introductory chapter presents a retrospect of the objects and work accomplished from 1865 to 1892, by a band of earnest and scientific workers interested in the progress of clinical medicine. It shows, that the prime motive was to encourage competitive, practical scientific studies of clinical medicine in the various schools of Europe, and to have the results published in book form as affording greater opportunity to the student than is allowed by the ordinary text book. That the original object has been, and is carried out can be seen by careful reading of the articles, all of which show earnest study and thought. We shall, as circumstances permit, present some of the most interesting and practical papers as abstracts.

CURRENT LITERATURE REVIEWED.

THE CHICAGO MEDICAL JOURNAL

For January contains an article on "Abscission of the Tonsil" by Dr. W. E. Casselbury. The indications for the operation are clearly shown together with its dangers. The technique of the operation is discussed and there are drawings of the author's tonsilotome and a special form of vulsellum forceps for grasping the tonsil, thus doing away

with the fork of the ordinary instrument, which the author regards as unsatisfactory.

There is also a paper by Dr. G. Frank Lydston on

Urethral Fever.

The causation of this obscure disease is due, according to the author to toxæmia "dependent on [a] imperfect elimination of the products of retrograde tissue metamorphosis; [b] to a greater or less degree of absorption of morbific materials produced by chronic inflammations and bacterial evolution, and the decomposition of residual urine behind the site of obstruction, i. e., pseudo-alkaloidal germ products." The various other theories as to its causation are reviewed in a somewhat lengthy article.

The other papers in the journal are: "The Relation of Nephritis to certain Cardiopathies," by Dr. Joseph M. Patton; "Is Medicine a Science?" by Dr. Edwin J. Kuh; and the report of a "Case of Exophthalmos associated with Nephritis," with a photograph of the patient, by Dr. Harold N. Moyer.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES FOR FEBRUARY.

The Cholera in Hamburg in 1892

is the title of a paper by Dr. F. Reiche, translated by Dr. A. A. Eshner. The source of the epidemic is discussed and thought to be the river Elbe, into which the sewerage of the city empties and from which the drinking water is taken. The history of the outbreak is carefully reviewed and there is a table of the daily number of cases with the daily number of deaths. The treatment as practised by the author at the New General Hospital is described, as are also the post-mortem appearances observed.

W. Soltau Fenwick, M. D., of London and Walker Overend contribute a paper on "The Production of the First Cardiac Sound in Mitral Stenosis." According to the authors the snap-like first sound is caused by the closure and tightening of the tricuspid valve. The reasons for this belief and the other theories regarding the origin of this sound are ably stated in the paper.

Dr. B. A. Randall, in a paper on

Pain in Otitis Media,

urges that, in any case of earache, the entire auditory tract be investigated with all possible stringency and the exact seat and meaning of the pain learned, as the preliminary to treatment. The careful inflation of the middle ear is advocated only after a thorough cleansing of the nares and pharynx; and for the relief of the aural condition he considers hot syringing as the best single measure. The article is short, pointed, and well worth the reading of the general practitioner who is so often called on to relieve the tortures of earache.

Dr. Frederick Peterson presents the claims of the "water treatment" in an article on "Hydrotherapy in the Treatment of Nervous and Mental Diseases." The general laws of for its administration, its indications and methods of application are fully set forth. Its applicability in insane patients receives special attention.

Drs. J. William White and A. C. Wood continue their contribution on

Methods and Results in Cases of Nepolasms, Vesical Calculi and Diseases of the Bones and Joints.

The report includes malignant tumors of the breast, sarcomata in the parotid gland, in the neck and in the foot; also cases of carcinomata and lipomata. In the treatment of vesical calculi, litholapaxy is advised in all suitable cases. A photograph of a stone is given which was too large to be grasped by the lithotrite and had to be removed by the high operation. The weight was nine and one-half ounces. Under diseases of the bones, cases of necrosis are reported and the treatment of various fractures and dislocations described. Diseases of the rectum are included in this report, hemorrhoids being treated by one of the three methods, clamp and cautery, ligation or excision, and the objections to each method tersely stated. Strictures of the urethra are discussed, the diagnosis and treatment described. As has been said in the notice of the first part of this paper, the cases reported have occurred in the service of Dr. White at the University Hospital. The paper is illustrated with photographs of patients and specimens removed.

Other papers in this month's journal are the report of a "Case of Congenital Elephantiasis of the Scalp," with a photograph of the patient, by Dr. Pedro S. De Magalhaes, of Rio Janeiro; and "The Diagnostic Significance of the Venous and Arterial Murmurs of the Neck," by Dr. James K. Crook.

THE NEW YORK MEDICAL JOURNAL

for January 21st, contains a very valuable paper by Dr. George M. Sternberg on

Disinfection at Quarantine Stations, Especially Against Cholera.

The methods used in New York in the late successful fight against the importation of cholera are fully described. The author considers dessication the best mode of killing the germs of cholera. Disinfection of the mails and merchandise is declared unnecessary, from a bacteriological standpoint, if the merchandise was clean and dry when received on shipboard and if it arrives in the same condition. The free exposure of the articles in the disinfecting chamber is of paramount importance, as neither hot air or steam penetrate bundles of clothing readily. "To the writer it appears that disinfection would be accomplished by the free exposure of woolen garments, blankets, etc., in a hot-air drying oven or chamber to a temperature of 80° to 100° C. for half an hour or more, being careful that no two articles were piled one upon another." Disinfection of clothing by steam on board ship is urged. The paper is well worth attention at this time when there is every prospect of an attempted invasion of our cities during the coming summer.

Dr. Charles Phelps contributes a paper (continued from the previous number of the journal) on "A Clinico-pathological Study of Injuries of the Head, with special reference to Lesions of the Brain Substance." A large number of fractures of the skull are reported, detailing the symptoms during life and the pathological conditions observed at the post-mortem.

Dr. William J. Fluhrer describes an "Improved Technique in the Operation of External Urethrotomy," illustrating his paper with cuts of the instruments used and the method of using them.

Other papers are: "The Value of Sprays in the Treatment of Catarrhal Affections of the Upper Air Passages," by Dr. Clarence C. Rice, and "Tumors of the Orbit and Neighboring Cavities," by Dr. Charles Stedman Bull.

In the issue of the same journal for January 28th, Dr. William A. Hammond discusses

Certain Organic Extracts,

particularly the far-famed Brown-Sequard Elixir, which the author claims, possesses decided virtues. For brain-tired people he would inject a concentrated extract of the brain of a healthy animal. These extracts can also be given by the mouth, but must be dropped upon the tongue, and so absorbed in the system without coming in contact with the gastric juice which destroys their power. The paper includes the report of cases where the author claims the patients were benefitted by the use of these extracts.

Dr. Charles Phelps concludes his exhaustive paper on "A Clinico-pathological Study of Injuries of the Head," the subjects considered being, Thrombosis of the Sinuses, Lacerations of the Brain, Contusion, Contre Coup, Concussion and Compression. The subject is entered into minutely and the diagnosis and treatment fully discussed.

Other papers in this issue are: "The After Results of Nasal Cauterization," by Dr. Thomas Amory De Blois; "A Case of Suppurating Ethmoiditis," by Dr. J. H. Bryan. The number concludes with some remarks by Dr. Ellsworth Eliot presented at a meeting of the managers of the New York Society for the Relief of Widows and Orphans of Medical Men.

SCRIBNER'S MAGAZINE.

The quite interesting sketch which forms the sixth instalment of the "Stories of a Western Town," is among the most entertaining of the contents of the February *Scribner's*. Several well illustrated articles of travel and matters incident thereto, attract attention. The "Personal Recollections of Charles Sumner" is a valuable paper. Literature of this sort has more than a transient value, and should be treated accordingly. Mr. Sumner was a strong figure among American Statesmen and in the politics of the day in which he lived, and recollections of his time are more than ordinary personal reminiscences—they are history.

THE DUBLIN JOURNAL OF MEDICAL SCIENCE.

The January issue of *The Dublin Journal* comes to us with several interesting papers. Dr. Joseph O'Carroll has a communication on "*Saturnine Encephalopathy*" of which fuller mention is made elsewhere.

Dr. Henry O'Neill in his article on the

Treatment of Large Arterio-venous Naevi

considers excision more suitable than ligation or electolysis, because—

1. All the nævoid tissue can be more rapidly and thoroughly removed, so that there is not likely to be a re-appearance of the nævus.
2. There is very slight hemorrhage, and it can be easily prevented or arrested by forci-pressure forceps and ligatures.
3. There is no slough left in the wound.
4. The wound heals rapidly. The same writer has as a second division of his subject the

Treatment of Epithelioma of the Lip by Excision, etc.

In presenting his cases of Epithelioma, five in number, he offers as his method in the treatment of this affection of the lower lip, where it has lasted over two months and where the glands can be felt beneath the lower border of the jaw and in front of the submaxillary gland, first to remove the enlarged lymphatic glands by an incision one and one-half inches long over the glands, parallel to the lower border of the jaw and close beneath it. When the lympathetic glands are enlarged and closely adherent to the submaxillary gland, he removes the latter, previously ligating in two places and dividing between the ligatures, the facial artery where it passes over the upper and posterior border of the submaxillary gland. By retracting the edges of the wound the glands can easily be removed by the finger, director and scissors. He then excises the epitheliomatous ulcer by cutting through the whole thickness of the lip and removing at least half an inch of the tissue to each side of the ulcer. He considers the removal of the affected glands beneath the angle of the jaw of equal importance to the removal of the primary epithelioma, because re-appearance of cancer takes place most frequently in these glands.

Dr. M'Ardle calls attention to a case of "Arrest of Development in Intra-uterine Life." The mother met with a railroad accident while travelling. Some five months and eighteen days after, she gave birth, a little before full term, to a child which showed arrested development of the head, spine, and right leg.

Dr. More's paper "Extensive Intestinal Ulceration in Typhus Abdominalis Ambulatorius, fatal by Convulsions on the ninth (?) day," completes this number.

THE OPTHALMIC REVIEW

for December, 1892, commences with an interesting original contribution by Charles A. Oliver on "Similarly placed Opacities of the Cornæ Occurring in Mother and Son." The

cornæ of the boy, eight years of age, presented dense, almost centrally situated opacities surrounded by an annulus or ring of superficial pin-dot opacities, without any trace of inflammatory vascularity, and unaccompanied by any other gross ocular lesions. Strangely enough the corneæ of the mother's eyes presented similar opacities.

Amongst the Reviews there is one upon three papers by Darier, of Paris, upon "Subconjunctival Injections of Corrosive Sublimate in the Treatment of various Diseases of the Eye." It is stated that marked benefit has been obtained in cases of iritis, irido-choroiditis, and various inflamatory conditions of the cornea by injecting one to two minims of a 1 to 1000 solution of corrosive sublimate beneath the conjunctiva.

There is also a Review of Allvar Gullstrand on the "Objective Method of Diagnosis in Paresis of Ocular Muscles." The method consists in a systematic comparison of the corneal reflection as seen in the pupil when the eyes are rotated in the various meridians of the fields of fixation. It is based on the well-known fact that a corneal reflex changes its position in the pupil when the eye moves and the reason that it does so is that the two objects, reflex and pupil, lie at different levels in the eyeball.

A notice of the November meeting of the "Ophthalmological Society of the United Kingdom," reports a discussion upon the "Intra-ocular Injections of Antiseptic Solutions." It was generally thought probable that in the use of intra-ocular injections a distinct advance in ocular therapeutics might be made.

NEWS AND MISCELLANY.

An Army Medical Board

will be in session in New York City, N. Y., during April, 1893, for the examination of candidates for appointment to the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War before March 15, 1893, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which, his Diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D. C.

C. SUTHERLAND,
Surg. Gen. U. S. Army.

American Electro-Therapeutic Association.

At the second annual meeting of the American Electro-Therapeutic Association, the following officers were elected for the ensuing year:

President, Dr. Augustin H. Goelet, 531 West Fifty-seventh street, New York; First Vice-President, Dr. Wm. F. Hutchinson, Providence, R. I.; Second Vice-President, Dr. W. J. Herdman, Ann Arbor, Mich.; Secretary, Dr. Margaret A. Cleaves, 68 Madison avenue, New York; Treasurer, R. J. Nunn, 119 York street, Savannah, Ga.

The third annual meeting will be held in Chicago on Sept. 12th, 13th and 14th, 1893. A cordial invitation is extended to all members of the profession interested in electro-therapeutics. Arrangements for special rates on railways and at hotels are in progress.

The Committee of Arrangements will be obliged if those who intend being present at the meeting will send their names, the class and amount of accommodation required, titles of papers to be presented, applications for membership, etc., at as early a date as possible. Accommodation should be secured early on account of the crowded condition of the hotels, because of the World's Fair. All communications should be addressed to the Secretary.

The committee will be glad to furnish any information in regard to the meeting upon application.

ARMY AND NAVY.

U. S. MARINE HOSPITAL SERVICE FOR THE FOUR WEEKS ENDING FEBRUARY 4, 1893.

Mead, F. W., Surgeon, to proceed to New London and New Haven, Conn., as Inspector, Feb. 4, 1893.

Carter, H. R., Surgeon, granted leave of absence for thirty days, Feb. 3, 1893.

Stoner, J. B., Passed Assistant Surgeon, to assume command of service at Portland, Oregon, Jan. 17, 1893.

Young, G. B., Assistant Surgeon, when relieved to proceed to Pittsburgh, Pa., for duty, Jan. 17, 1893.

Cofer, S. E., Assistant Surgeon, placed on "waiting orders," Jan. 23, 1893.

Eager, J. M., Assistant Surgeon, to proceed to Cape Charles Quarantine for temporary duty, Feb. 3, 1893.

Stewart, W. J. S., Assistant Surgeon, to proceed to Norfolk, Va., for temporary duty, Feb. 1, 1893.

DEATH.—Passed Assistant Surgeon Spencer C. Devan died February 3, 1893, at Philadelphia, Pa.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & Co.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.
(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

Pil. Lady Webster.
(WM. R WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.
(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.
(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

The Demand For

a pleasant and effective liquid laxative has long existed—a laxative that would be entirely safe for physicians to prescribe for patients of all ages—even the very young, the very old, the pregnant woman, and the invalid—such a laxative as the physician could sanction for family use because its constituents were known to the profession and the remedy itself had been proven to be prompt and reliable in its action, as well as pleasant to administer and never followed by the slightest debilitation. After a careful study of the means to be employed to produce such

A Perfect Laxative

the California Fig Syrup Company manufactured, from the juice of True Alexandria Senna and an excellent combination of carminative aromatics with pure white sugar, the laxative which is now so well and favorably known under the trade name of "Syrup of Figs." With the exceptional facilities, resulting from long experience and entire devotion to the one purpose of making our product unequalled, this demand for the perfect laxative

is met by Our Method

of extracting the laxative properties of Senna without retaining the griping principle found in all other preparations or combinations of this drug. This method is known only to us, and all efforts to produce cheap imitations or substitutes may result in injury to a physician's reputation, and will give dissatisfaction to the patient; hence, we trust that when physicians recommend or prescribe "Syrup of Figs" (Syr. Fici Cal.) they will not permit any substitution. The name "Syrup of Figs" was given to this laxative, not because in the process

# of Manufacturing

a few figs are used, but to distinguish it from all other laxatives, and the United States Courts have decided that we have the exclusive right to apply this name to a laxative medicine. The dose of

"SYRUP OF FIGS"

as a laxative is one or two teaspoonfuls given preferably before breakfast or at bed time. From one-half to one tablespoonful acts as a purgative, and may be repeated in six hours if necessary.

"Syrup of Figs" is never sold in bulk. It is put up in two sizes to retail at fifty cents and $1.00 per bottle, and the name "Syrup of Figs" as well as the name of the California Fig Syrup Company is printed on the wrappers and labels of every bottle.

THE PARASITIC THEORY OF THE ETIOLOGY OF CARCINOMA.*

ROSWELL PARK, A. M., M. D.,† Buffalo, N. Y.

In any discussion on cancer the question of its etiology should always take precedence of that concerning its treatment, since the latter to be both rational and effective should be based upon the former. It is not my purpose at present to consider the numerous theories put forward in time past to explain its essential cause, but rather to invite your attention to a *resume* of the latest and perhaps most fascinating explanation offered as to the prime cause of this dreadful malady.

Just who is entitled to the credit of having first advanced the hypothesis of its parasitic origin it would be hard to tell, but to two English surgeon pathologists, Hutchinson and Paget, we are largely indebted for having advanced the *a priori* plausibility of such a view. In a memorable address some years ago, the latter called attention to the parasitic origin of most of the xylomata or woody tumors seen on so many trees, and ventured the prediction that an analogous parasitic origin would ere long be determined for many of the tumors met with in the animal kingdom. That we now have a class of infectious granulomata acknowledged by all, is not yet sufficient realization of such a prophecy. Virchow recognized so early as 1847, certain peculiar bodies noted in and between carcinoma cells, which he then supposed to be evidences of degeneration. Their true nature was not made out until 1888, when they were identified as belonging to the sporozoa, although he himself later (*Virchow's Archiv*, Bd. 33) suggested the possibility of their being psorosperms.

Inasmuch as the present paper deals mainly with these organisms, it will be proper to stop here a moment to rehearse a few statements concerning their nature and place in the animal kingdom.

First of all they are distinctly *not bacteria* which are vegetable organisms, but belong to the *protozoa* or unicellular *animal* forms.

The *Gregarinidæ* are included in the sub-order Endoplastica and sub-class Sporoza, according to Lenckart, and are described as having ovoidal or spheroidal bodies, sometimes with a segmental constriction, occasionally with one end beaked and carrying horny spines. They consist of a dense ectosarc and a softer endosarc, containing an endoplast but no contractile vacuole. They are essentially parasitic. They have no oral aperture nor pseudopodia. They contain granular protoplasm with nucleus and nucleolus, and vary in size even up to a centimeter in diameter. The *Coccidia* form another sub-class of the Sporozoa, are quite similar to the above, but have a micropyle at one end.

According to another classification the Sporozoa or Cytozoa are divided into four sub-classes as follows:

* Read before the New York State Medical Society, February 8, 1893.

† Professor of Surgery, Med. Dept., University of Buffalo; Attending Surgeon, Buffalo General Hospital, etc.

Gregarinidea (by some held to include the coccidia.)

Coccidiidea or Microsporidia.

Myxosporidia.

Sarcocystidia or Sarcosporidia.

But minutiæ of classification aside, it is enough for our present purposes that the bodies in question are exceedingly minute forms of unicellular animal life. In 1878 Rivolta (*Dei parassiti vegetali*, Turin, 1878,) and Bollinger (*Virchow's Archiv.*, Bd. 58,) recognized their parasitic nature and identified them as gregarinæ; and they gave to the lesions found in fowl and pigeons which so closely resemble molluscum, the suggestive name *Epithelioma gregarinosum*. In 1880, Nedopil, Herisson and others thought to characterize miliary carcinomatosis as an infectious disease. Neisser, in a study of molluscum contagiosum (*Vierteljahrschft f. Dermatol*, 1888, XV. 553) distinguished between their spores and better developed stages. He only studied them in sections, his culture and inoculation experiments failing. He found them in greatest number in affected tissues, but also in uninjured cells and adjacent tissues.

L. Pfeiffer described, also in 1888, (*Zeitschft. f. Hygiene*, 1888, III., 3 and IV., 442) certain bodies met with in two cases of general carcinosis and one of sarcoma of the breast, and regarded them as belonging to the Sporozoa. He found them in the epithelial cells of a fresh, warm melanotic growth, and studying their developmental stage saw that it resembled closely true spore formation of the micro-sporidia. (See also *Die Protozoen als Krankheitserreger*, Jena, 1890.)

Darier, in 1889, observed certain bodies which he believed to be coccidia in a hitherto undescribed skin disease to which he gave the name *Psoro-spermose folliculaire vegetante* (*Annales de derm et de syph.*, 1889, No. 7), and later, with Wickham (*Centrlbl't f. Path. Anat.*, I., 682,) he attributed Paget's disease of the nipple to a coccidium which invades the skin.

It would certainly seem as though, providing Paget's disease of the nipples be a factor in the production of certain mammary cancers and that it be a true psorospermosis, the best conditions for a study of the parasitic nature of cancer would be met with in cases of this disease.

Hutchinson, Jr., (*Trans. Path. Soc.*, London, XLI, 1890, 214) and Wickham (*Archives de med. experimentale*, 1890, I., 1; *Annales de dermat et de syph.*, 1890. I and II) have both studied the matter carefully, the latter with seven cases. Wickham describes three stages of the disease after invasion:—

1. Thickening and disorganization of the epidermis and inflammation of the corium.

2. Elevation of the horny cells, lively escape of leucocytes which crowd aside the epithelial cells, proliferation of the rete mucosum and the epithelium of the sweat, sebaceous and milk glands, and finally extensive infiltration of the cutis.

3. Stage of true carcinomatous growth from both the superficial and glandular epithelium.

In the beginning the parasites appear with or without nuclei, later surround themselves with a double membrane, while the contained protoplasm differentiates itself into a number of granules, and thus is formed what he calls a sporiferous cyst. These he found not only in the epidermis, but also in various gland ducts and in the pearly bodies. This in spite of failure to cultivate or inoculate.

Darier and Wickham did not doubt their parasitic as well as their pathogenic character, and felt that under their influence not only epithelioma but other forms of carcinoma might develop.

Malassez and Albarran found in two epitheliomata of the jaw peculiar bodies having striking resemblances to the coccidia so often found in the livers of rabbits (*Soc. de. Biol.*,1889, Avril), and Vincent had a similar experience (*Annales de micrographic*, 1890, II. p. 10.)

Thoma found in the nuclei of many cancer cells peculiar bodies so different from other human cells that he considered them parasitic and thought they might be encapsulated coccidia (*Fortschrit d. Med.* 1889, p. 413.)

Sjörbring of Lond, (*Ibid.* p. 529) studied their life history and found free extra-cellular as well as intra-cellular and spore forms, and called attention to their resemblance to the organisms which produce *pebrine* in silkworms. Steinhaus examined thirty cancers from various sources, sometimes finding these bodies, sometimes not, but considered them parasitic when present. (*Virchow's Archiv.*, Bd. 126, p. 533.)

Hacke described, in 1890, four cases of cancer in which he found coccidia in and among the cells, varying in size from two to fifty microns, the smaller intra—the larger extra—cellular, spherical, encapsulated, the capsule very highly refractive. Within the cell they often appeared as in a vacuole, owing to the shrinking of the surrounding protoplasm during hardening. As they grew they seemed often to fill and destroy the cell (*Soc. de. Biol.*, 1890, Nov. 8.)

Van Henkelom, of Leyden, studied some two hundred tumors and came to conclusions essentially those of Thoma and Sjörbring (*Centrlblt f. Path. Anat.*, 1890, p. 704.)

But these views were not accepted without lively dispute. Russell, Pifford, Schütz (*Microscopische Carcinombefunde.* Frankfurt, 1890), Török and Tommasoli, among others, after minute study claimed that these so-called coccidia were only altered cells, simple masses of chromatin, products of degeneration, etc. Klebs made implantation experiments without success, and these bodies underwent no change nor increase. Duplay and Cazin finding no such changes as they thought coccidia in their evolution should evince, concluded these bodies to be of degenerative origin and to result not only from cells but from mitoses.

Ribbert made a most exhaustive study (*Deutsche med. Wochschft.*, 1891, p. 1179) of cell inclusions in cancer and concluded that his results did not permit his acceptance of the parasitic theory, and therefore held to the degenerative view of their nature.

Ramsay, Wright (*Centrlblt f. Allgem. Path.*, 1890, No. 11) and Russell (*Br. Med. Jour.*, 1890, p. 1297), while not so opposed to the parasitic view, referred these bodies to the saccharomyces. Moreover the latter found among them certain granules which have an affinity for fuchsin, the so called "fuchsine bodies" (fuchsinophile) which are also to be found in other pathological and in normal tissues.

Cornil (*Journal de l'anat et de physiol.*, 1891, No. 1) and Hausemann (*Virchow's Archiv.*, Bd. 123, p. 356, 1890) think it possible to mistake for coccidia or their spores, various stages of karyokinetic cell division.

Strobe (*Ziegler's Beiträge*, 1891, xi, Hft. 1) and Steinhaus (*Centralblt f. Allgem Path.* 1891, No. 2) feel compelled to admit the sporozoan nature of these bodies, but are not convinced they are the true cause of cancer. * * * *

Since 1890 scarcely an article has appeared on the subject of cancer bacilli, and the attention of all workers in this field seems to have been concentrated on the sporozoa which are alleged to cause the disease.

Inasmuch as everything now points in their direction, it will be worth while to refer briefly to methods for their detection. Pieces of cancer tissue should be preserved in Flemming's solution, which seems to cause the organisms to appear to better advantage. The stain which gives the best result is the so-called Ehrlich-Biondi triple stain, whose formula is simple but whose happy combination seems difficult. The directions given are to dissolve

Methyl green	0.5	in distilled water.	100,
Acid fuchsin	0.5	" "	40,
Orange	2.0	" "	200;

these solutions to be mixed and filtered before use. Sections are left in it for twelve hours, then washed, dehydrated, cleared and mounted. With this stain the nucleus of the cancer will become green, the protoplasm orange-red; the nucleus of the parasite red and its protoplasm light-blue. Puffer, Walker and many others have not hesitated to pronounce the included bodies to be true parasites. * * *

Herewith is concluded a necessarily incomplete brief summary of our present knowledge bearing on one of the most important topics now or ever before our profession. While the parasitic theory is by no means new, the facts which tend to substantiate it are of very recent discovery; so recent in fact that it would be folly to accept them as all sufficient. Obviously they can but constitute a mere foundation upon which we may hope to build. The other all-important yet subsidiary topics of the geographical distribution of cancer, and the influence of sex, age, part involved, civil and sanitary condition, injury, heredity, state of nutrition, and of preceding benign growth, must be constantly borne in mind. Many apparent contradictions must be explained; many conflicting statements reconciled.

The proper position for the real student, it would seem to me, is in the middle ground between skepticism on the one

hand and credulity on the other, waiting and working for the light that we have great reason to eagerly expect, and probably from the direction indicated in the course of this paper.

For my own part I cannot help feeling that we are on the eve of great discoveries in this matter, partly, perhaps, because I have for years had a growing conviction that cancer—and syphilis too—are parasitic diseases due to either unfamiliar or yet unknown organisms, and that some new technical method or some new application of old methods would ere long furnish the key to the mystery. Whether we have been recently supplied with this by the investigators quoted above is as yet uncertain, though probable.

How anxiously impatient yet sanguine I am you may better appreciate when you recall that my home is in a limited area where the death rate from cancer is greater than in any other part of our continent.

THE MANAGEMENT OF SUPPURATION COMPLICATING TUBERCULOUS DISEASE OF THE BONES AND JOINTS.*

V. P. GIBNEY, M. D.

From frequent analyses of cases treated in the hospital I do not hesitate to present my views without a statistical backing. The claim is often made by my colleagues in orthopædic surgery that suppuration can be prevented by the *timely* use of apparatus. At times I have been strongly tempted to make this claim myself. The whole question hinges on what we understand by the term *timely*. It will be readily admitted by medical men as well as surgeons that, if a case of tuberculous bone lesion in the neighborhood of the joint can be recognized very early and before any deformity arises, adequate protection to the joint will certainly contribute largely to the prevention of suppuration. The value of rest to any inflamed tissue has been established too long for any cavil at this late date. A difference of opinion often exists as to what is and what is not absolute rest to a part, one surgeon claiming that the apparatus he employs affords perfect protection even if *absolute* rest is not maintained, while another claims that perfect protection can not be secured unless *absolute* rest is maintained.

Take, for instance, the appliances used in the treatment of tubercular ostitis of the hip, or what is commonly known as "hip disease." The long splint, with which all are familiar and which forms the chief element in the American method of treating the disease, does not absolutely rest the joint, but permits a small range of motion however snugly applied. The traction employed by means of this apparatus depends largely upon the surgeon himself. Many who use it do not believe that it is possible to get a sufficient amount of traction to separate the articular surfaces, and claim that it gives only a sufficient amount of traction to prevent trauma. On the other hand, there are some who believe that it is possible to make the traction such that the articular surfaces seldom, if ever, came in contact. From a personal knowledge of the manner in which this splint is employed, my own belief is that the protection is seldom perfect, but that it is sufficient to guard the joint against trauma if the surgeon himself looks after the dressings, and makes the parent or nurse acquainted with the principle involved. This means, of course, intelligent co-operation.

The Thomas splint does not make any traction on the joint, but is simply a fixation appliance and must, of necessity, make a lever of the limb. And to do this it is difficult for one to see how the joint can help being injured more or less by contact of articular surfaces. It is claimed that the employment of axillary crutches is sufficient to guard against this evil, yet when one considers how little time during the twenty-four hours the patient is on the axillary crutches, he can readily understand the nature of some of the objections to the apparatus.

The combination of the long splint with

*Read before the New York State Medical Society.

the Thomas apparatus, theoretically, affords absolute rest as well as protection to the joint, and would seem to be all that is desired; yet the difficulty of adjusting, and the confinement of the whole body serve to make such a combination apparatus really of little practical value.

It is nevertheless true that with any of these forms of apparatus mentioned, the large proportion of cases, taken in the early stage and before deformity has arisen, do proceed to a cure without suppuration, and eventually, in many instances with complete restoration of the functions of the joint. On the other hand, it is just as true that there are cases taken in the very early stage, with the most approved forms of apparatus and with the most skillful men in charge of the same, that do go on to suppuration in spite of all we may do. We are in the habit of speaking of such cases as severe from the beginning. We speak of the lesion as a large one, involving three or four centres in the end of the bones and rapidly encroaching one upon the other. Thus much for the prevention of suppuration.

Our knowledge of the nature of tuberculous suppuration in a bone enables us to fix pretty definitely upon the locality, but the location of an abscess is not always a guide to the seat of disease. Small abscesses attended with very little constitutional disturbance one can safely treat expectantly; can treat the joint itself by protective apparatus and look upon the pus collection as of minor importance. In the preantiseptic day surgeons, as a rule the world over, were content to leave bone abscesses alone unless they became acute or very extensive. The surgical rule to *let out pus wherever found* did not apply to cold abscesses, and it was only occasionally that a bold surgeon advocated immediate interference. Since the advent of antisepsis it has been the custom to incise more freely, and there are many surgeons to-day who believe it good practice to operate whenever a pus collection is found. Yet there are a very respectable number, whose experience has been large, who still hesitate to operate unless constitutional symptoms develope.

It may be safely said of the Orthopædic Surgeon that *early interference is exceptional.* It is claimed by some of these gentlemen that adequate protection to the joint limits the suppurative process and does away with the necessity for incision. A rather extended personal experience has prejudiced me somewhat in favor of the aspiration of small abscesses, without the injection of any fluids or agents. I am satisfied that the percentage of cure is fifty per cent. The results of the introduction of iodoform in the various emulsions has not encouraged me in recommending this procedure. My plan in aspirating is about as follows: Use a good sized sterilized needle; go fearlessly and quickly into the sac, evacuate completely if possible, if not, incompletely; apply over the skin a basket strapping of rubber adhesive plaster—the straps drawn tightly; a roller bandage over this; keep the patient in bed for twenty-four hours with an ice bag over the parts, then let him go about with the apparatus properly adjusted. At the end of a fortnight repeat the operation with same after treatment. From three to six aspirations usually suffice to effect a cure.

Where a cure is not affected in this way I resort to a free incision; expose to view as much of the sac as possible; dissect away or currette with a flush gouge; dry the parts thoroughly with antiseptic gauze; pack lightly with iodoform, dermatol or boracic acid gauze, and over all this a full dressing. Remove the packing in about forty-eight hours; bring the edges of the wound together throughout the greater part of its extent, leaving an opening a half inch in length into which a drainage tube or gauze tent is inserted and redress every three or four days.

My experience in attempting complete removal of the sac and closure for primary union has not been sufficiently encouraging to lead me to speak favorably of this method. In many instances where I have secured primary union, and where the immediate result has been brilliant, the sac has refilled at a later period; I have been compelled to open the wound anew and do a bone operation, either gouging thoroughly or excising.

Where the abscess is in close proximity to the lesion, it is best, in my judgment, to do a bone operation at once, aim to remove the diseased portion and pack the cavity as in an abscess remote from the bone lesion. Roughly speaking, I should say at least fifty per cent. of abscesses opened in the manner above described,

wherein no attempt has been made to treat the bone itself by operatic measures, fifty per cent. of these cases, I say, come to the bone operation, generally as a life saving measure.

After all, I am not eager to interfere with these small abscesses, and prefer to keep them under observation, with protective apparatus to the limb, for a long time before interference; and, in a fair proportion of cases, the sac grows smaller or becomes more dependent and opens spontaneously with excellent result. So that I am in the habit of recommending to my class at the Polyclinic non-interference unless the surgeon is fully equipped for the details of antiseptic technique.

In the large multilocular abscesses that I meet for the first time, my plan is to incise at once, reduce the cavity if possible to a sinus or sinuses, establish good drainage, and at a later date attack the bone. If, however, the patient's condition is unfavorable I do not hesitate to attack the bone as soon as I open the abscess. These remarks apply more especially to tubercular disease of the hip-joint, and naturally lead up to the question of excision.

Notwithstanding the abundance of literature, both statistical and clinical, on this subject we are not as yet in possession of sufficient knowledge to enable us to determine when to excise and when not to excise. The final results of this operation, so far as I have been able to understand them, do not encourage me to advocate excision in all cases where extensive abscesses are present. In hospital work I have learned to rely upon the conditions of the patient, upon his behavior under expectant treatment for a while, upon the condition of the urine—that is the persistence of a low specific gravity and upon the probable extent of the disease. The cases most suitable, in my judgment, are those wherein the abscess appears in the gluteal region, is limited to this area and where one can readily get down upon the bone and secure the best drainage. Such cases, as a rule, present on section a limited area of disease, and whether one attempts complete eradication or partial, the results are usually good.

The class of cases that are most obstinate and that cause me to hesitate a long time, are those where the abscess appears in the groin in Scarpa's space, or on the inner side of the thigh. The pus sacs usually encroach extensively upon the femoral vessels and, as a rule, involve not only the head and neck, but a portion of the shaft. It is next to impossible to remove all the offending material, and very difficult to get healing from the bottom by reason of the number of pockets that have formed in the neighborhood of the joint. In a few instances I have adopted the plan recommended by my friend Dr. Poore, of New York, namely, curetting the shaft of the femur and making a counter-opening above the knee. My results have not been as good as he has obtained and hence the measure has not met with my cordial approval. In a few instances I have curetted the bone without making the counter-opening; have kept the shaft well packed with iodoformized gauze, subsequently with drainage tubes. A small proportion of such cases have done well, and I feel encouraged to continue this procedure.

The class of cases that are suitable for partial arthrectomy and gouging of bone is very small. In a number of instances I have been compelled to follow with a complete excision weeks or months after the partial operation, and my experience, therefore, coincides with that of surgeons who have written upon this subject.

In the management of suppurative disease above the knee joint, I can speak quite confidently of what is known as the expectant plan. That is this: Correct deformity by gradual extension, either in bed with the weight or pulley, or with extension apparatus; aspirate when pus is detected; follow this up by incision if the aspiration fails; drain thoroughly. Follow this procedure up by gouging out the foci of disease, packing from the bottom, and in every instance, if possible, endeavor to preserve the component parts of the joint. All of my operations upon the knee in children are supplemented by protective apparatus and a long course of such treatment. These remarks apply especially to the disease as it occurs in children. In adults I favor excision, rather than a partial or complete arthrectomy.

In suppuration involving the bones of the ankle joint in children, it makes little difference whether one incises abscesses or removes foci of disease in the bone, so far as the ultimate result is concerned. I am convinced, from a long study of these cases, that the rule is a recovery with a

joint practically perfect. In no instance, I am satisfied, is it ever necessary to amputate the leg for disease in adults. Where one can be satisfied that bones within reach are alone involved, then a partial operation with fixation of the joint for many months thereafter does result in a cure. Yet one can never feel satisfied that all of the bones diseased have been reached, and hence the necessity for more stringent measures.

I have said nothing thus far on the tuberculous disease of the bones of the spinal column, but the same treatment is applicable here as in the bones already mentioned. I do believe, if one treats the back with a splint for a long period of time, that the abscess sacs are easily managed and that in a large percentage of cases a cure will result. By splinting the back I mean the continuous and uninterrupted employment of an apparatus that will prevent motion and deformity. It is not sufficient to apply a brace or a jacket that can be removed at will by the parents or friends, for the reason that abuses are bound to occur and disappointment will follow.

In concluding let me summarise as follows:

(1.) Protect the joint about which the bone lesion exists in the early stage and in the later stages, whether the abscess is let alone, aspirated or incised.

(2.) In cases where the suppurative process is confined to a small area, it is good surgery to leave the small abscesses alone if the protective appliance is adequate.

(3.) It is good practice to aspirate where the abscess is in the way of the proper adjustment of apparatus, and by such procedure one may expect good results in at least 50 per cent. of the cases aspirated.

(4.) The simple incision of an abscess dependent upon bone disease depends for good result upon the extent of the bone lesion.

(5.) Excision of the hip is not a measure to be employed in all cases where extensive suppuration exists, but must depend largely upon the condition of the patient and the location and extent of abscesses.

(6.) Expectant treatment for the knee and ankle joint in children yields the best results for life and limb.

(7.) Amputation of the ankle in a child is rarely ever justifiable except when amyloid disease of liver or kidneys threatens or is present; of a hip after a thorough excision has failed.

(8.) The long continued employment of a good fitting splint to the back in Pott's Disease of the spine will yield better results than any operative procedures on the bone with which I am familiar.

CLINICAL LECTURES.

ON CERTAIN ANIMAL EXTRACTS: THEIR MODE OF PREPARATION AND PHYSIOLOGICAL AND THERAPEUTICAL EFFECTS.*

WILLIAM A. HAMMOND, M. D.†

Gentlemen:—I wish I could believe all the pleasant things that my friend, Professor Roosa, has, in the goodness of his heart, just said about me. There are two expressions of his, however, which I know to be true. First, I scarcely need any introduction here, for though I have been away from you for more than four years, I feel that I am, if only for an hour or so, back among my own people and I experience something of the emotions of the captain who walks the quarter deck of his ship. Second, I am one of the founders of this school. I shall always regard that fact as the most honorable of all the events of my professional life—the one in which I take the most pride. The excellence of the work done here by the faculty and the phenomenal success that has attended

* Lecture delivered at the New York Post-Graduate Medical School and Hospital, January 16th, 1893.

† Surgeon-General U. S. Army (retired), late Professor of Diseases of the Mind and Nervous System in Institution mentioned.

upon their labors are circumstances of which they may well feel a justifiable elation and in which emotion I claim the right to share.

But I am not here to-day to speak of the triumphs of this school. I want to tell you of some of the work upon which I have been engaged since I left you, and the story will, I think, interest a body of physicians like yourselves who come here to learn new facts and thus to keep abreast with the progress of the age. You remember that about three and a half years ago Dr. Brown-Séquard electrified the medical and non-professional world by announcing that the expressed juice of the testicles of the guinea pig was an agent capable, when injected into the blood, of arresting to some extent the inroads of old age and of curing certain diseases to which mankind is subject. I at once entered upon a series of investigations of the matter, some of the results of which are published in the *New York Medical Journal* for August 13th, 1889. I became convinced that we had in the juice of the organs in question a means of acting upon the body in a manner and to an extent different from that of the effects of any other substance previously known to medical science.

But, though surprising in its action, I found that there were certain practical difficulties in the way of the fresh testicular juice ever becoming of general use in actual practice.

In the first place it had to be used fresh, for if not, there was great danger of a putrefactive process being set up and blood poisoning produced, and this was the result in several cases in which it was used in this country. In large cities there is almost an impossibility of getting the organs in question immediately on their being removed from the animal.

Secondly, it was extremely difficult to filter the thick juice, even when diluted according to Brown-Séquard's directions. Filtering paper would not do, for the morphological constituents passed through and an abscess was very liable to be produced at the point of injection. A porous stone filter absorbed the juice and none of it came through, as there was never a sufficient quantity to saturate the stone and to pass through it. A large amount could not properly be made at one time, as it would not keep, so that it was necessary at every *séance* to prepare a fresh quantity.

After a time, therefore, during which I did my best with the fresh juice; using for this purpose the testicles of the ram and creating several abscesses with febrile disturbance, I gave up this method and turned my attention to preparing extracts not only of the testicles but of other organs of the body. It would be to some extent instructive to go over my failures, but I have not time for that. I can only on this occasion tell you of my success and the conclusions I have arrived at in regard to the subject. And I shall mainly confine my remarks at present to the consideration of one extract, that of the brain, which for convenience I designate "cerebrine." I will merely say that I have prepared extracts also of the spinal cord,—"medulline;" the testicles,—"testine;" the ovaries,—"ovarine;" the pancreas,—"pancreatine;" the stomach,—"gastrine," and the heart,—"cardine," and that I am nearly ready to give to the profession the results of my observations with these substances. Of course the kidneys and the liver being excretory organs, can not properly be used for the purpose of making extracts to be introduced into the blood. Were we to use them in this manner we should be putting back into the system poisons which it had eliminated, and hence would produce disaster, and perhaps, even death.

The process of preparation of the extract of these several organs, while individually somewhat different, does not materially vary from that used for the brain, which is as follows:

The whole brain of the ox after being thoroughly washed in water acidulated with boric acid, is cut into small pieces in a mincing machine. To one thousand grammes of this substance, placed in a wide-mouth glass-stoppered bottle, I add three thousand cubic centimetres of a mixture consisting of one thousand cubic centimetres each of saturated solution of boric acid in distilled water, pure glycerine and absolute alcohol. This is allowed to stand in a cool place for at least six months, being well shaken or stirred two or three times a day. At the end of this time it is thrown upon a porous stone filter through which it percolates very slowly, requiring about two weeks for entirely passing through. The residue remaining upon

the filter is then enclosed in several layers of asceptic gauze, and subjected to a pressure of over a thousand pounds, the exudate being allowed to fall upon the filter and mixed with a sufficient quantity of the filtrate to cover it. When it has entirely filtered it is thoroughly mixed with the first filtrate and the process is complete.

During the whole of this manipulation the most rigid antiseptic precautions are taken. The vessels and instruments required are kept in boiling water for several minutes and are then washed with saturated solution of boric acid. Bacteria do not form in this mixture under any circumstances, but it is necessary to examine it from time to time microscopically, in order to see that no foreign bodies have accidentally entered. Occasinally, owing to causes which I have not determined, though I think it is due to variations in temperature, the liquid becomes slightly opalescent from the formation of a flocculent precipitate. It sometimes takes place in a portion of the extract kept under apparently identical conditions with other portions that remain perfectly clear. It can be entirely removed by filtration through Swedish filtering paper, previously sterilized, without the filtrate losing anything of its physiological or therapeutical power.

Five minims of this extract diluted at the time of injection with a similar quantity of distilled water constitute a hypodermic dose.

The most notable effects on the human system of a single dose are as follows—though in very strong, robust, and large persons, a somewhat larger dose is required, never, however, exceeding ten minims:

1. The pulse is increased in the course of from five to ten minutes, or even less in some cases, by about twenty beats in a minute, and is rendered stronger and fuller. At the same time there is a feeling of distention in the head, the perspiration is largely increased, the face is slightly flushed, and occasionally there is a mild frontal, vertical, or occipital headache or all combined, lasting, however, only a few minutes.

2. A feeling of exhilaration is experienced which endures for several hours. During this period the mind is more than usually active and more capable of effort. This condition is so well marked that if a dose be taken about bedtime wakefulness is the result.

3. The quantity of urine excreted is increased, when other things are equal, by from eight to twelve ounces in the twenty-four hours.

4. The expulsive force of the bladder, and the deristaltic action of the intestines are notably augmented, so much so that in elderly persons in whom the bladder does not readily empty itself without considerable abdominal effort, this action is no longer required, the bladder discharging itself fully and strongly, and any existing tendency to constipation disappears, and this to such an extent that fluid operations are often produced from the rapid emptying of the small intestine.

5. A decided increase in the muscular strength and endurance is noticed at once. Thus, I found in my own case that I could "put up" a dumb-bell weighing forty-five pounds fifteen times with the right arm and thirteen times with the left arm, while after a single dose of the extract I could lift the weight forty-five times with the right arm and thirty-seven times with the left arm.

6. In some cases in elderly persons an increase in the power of vision is produced, and the presbyoptic condition disappears for a time.

7. An increase in the appetite and digestive power. Thus, a person suffering from anorexia and nervous dyspepsia is relieved of those symptoms, temporarily at least, after a single dose hypodermically administered.

These effects are generally observed after one hypodermic injection, and they continue for varying periods, some of them lasting for several days. In order that they may be more enduring, two doses a day should be given every day or every alternate day, as may seem necessary, one in the morning and one in the afternoon, and kept up as long as the case under treatment seems to require. The most notable effects are seen in the general lessening of the phenomena accompanying advancing years. When some special disease is under treatment, the indications for a cessation of the injections will be sufficiently evident, either by an amelioration or cure.

To the substance obtained in this manner and held in solution, I have given, as stated, the name of "Cerebrine" as the

one, in view of its origin, most appropriate.

I have employed the solution of "Cerebrine" with curative effects in many diseases of the brain and nervous system. It is almost specific in those cases of nervous prostration—the so-called neurasthenia—due to reflex causes or excessive mental work, or persistent and powerful emotional disturbance. A hypodermic injection of five minims, twice daily, continued for two or three weeks, and without other medicine, being sufficient to produce cure. It has proved equally effectual in cases of cerebral congestion, in which the most prominent symptom was insomnia, sleep being produced usually in the course of two or three nights. I have also employed it successfully in migraine, hysteria, melancholy, hebephrenia—the mental derangement occurring in young people of either sex at the age of puberty—in old cases of paralysis, the result of cerebral hemorrhage. In neuralgia, sciatica, and in lumbago, it has acted like a charm, except in one case of facial neuralgia, in which it did not appear to be of the slightest service.

I have employed it in eleven cases of epilepsy. Three of these were of the *petit mal* variety; in two the effect has been so marked that I am not without the hope that cures will result, although I am not able, as yet, to speak positively on this point, the patients having been less than a month under treatment. In the other no influence appeared to be produced.

Eight cases were of the *grand mal* variety. In two of these the number of paroxysms has been reduced more than one-half, and greatly mitigated in severity. In six other cases which were of long duration I could perceive no curative effects.

In a case of general paresis no therapeutical influence was apparent beyond that of arresting the delusions of grandeur for a few days. In a case of hebephrenia, however, occurring in the person of a young lady eighteen years of age, the effect has been most happy, the symptoms entirely disappearing in a little more than a month's treatment.

In several cases of nervous prostration, the result of long-continued emotional disturbance, and in which there were great mental irritability, dyspepsia, physical weakness, loss of appetite and constipation, relief was rapidly afforded. In three other cases in which the most notable symptom was functional cardiac weakness, the effect has been all that could have been desired. In these cases it was employed in conjunction with "Cardine," the extract of the heart of the ox, made in the manner already described.

It is not my intention at the present time to bring before you all the points of this interesting subject, or to allude further to experiments in the treatment of other diseases, which are not yet concluded. In the near future I shall enter more largely into the consideration of the matter in all its details. I will only add now that I have used with excellent results in cases in which it seemed to be indicated, the extract of the testicles of the bull and also that of the pancreas of the ox, and these investigations also will be given to the profession at an early day. The first named of these—"Testine"—I have found to be of the greatest efficacy in the treatment of sexual impotence when it has been the result of venereal excesses, and in cases of too frequent noctural seminal emissions.

It has recently been alleged by some medical authorities, that there is no difference in the physiological or theraputical action of medicines, whether they be introduced directly into the blood by hypodermic injections or taken into the stomach, but it is scarcely worth while to seriously combat this assertion.

For while it may be true that some substances are not altered by the gastric juice before they are absorbed into the system, it certainly is not true of many others, and it surely is erroneous as regards those of animal origin. Indeed it is, I think, doubtful if anything capable of being acted upon by the gastric juice and of being absorbed into the blood gets into the system in exactly the same form in which it got into the stomach. And I am very sure that all organic matters, without exception, undergo radical changes under the action of the gastric juice, in some cases amounting to decomposition and recomposition.

It is well known that Woorara, the virulent arrow poison used by the Indians of South America, and which is invariably fatal to animal life when injected into the blood, is innocuous when taken into the

stomach, even in very large quantity. I have ascertained, by actual experiment, that the poison of the rattlesnake may be swallowed with impunity. During the course of my medical service in the army on the Western plains, I have collected a large quantity of rattlesnake poison. A small fraction of a grain of this injected hypodermically was sufficient to kill a dog in a few minutes, while previously the same animal had been made to swallow a half a drachm without the production of any apparent result. Experiments made with the saliva of hydrophobic animals prove that it is rendered harmless by the action of the gastric juice. The vaccine virus may certainly be swallowed with impunity, as has been shown by repeated experiments upon animals.

Relative to the animal extracts to which I am now referring, I have ascertained beyond question that if they are inclosed in capsules so as to reach the stomach without coming in contact with the mucous membrane of the mouth, they are absolutely without physiological or therapeutical effect so far as can be perceived, even when given in quantities of a teaspoonful or more, but if dropped upon the tongue in double the quantity used for hypodermic injection and allowed to remain in the mouth without being swallowed—thus avoiding the action of the gastric juice—they are absorbed and exert a slower but still decided effect, though nothing comparable to that produced when they are administered hypodermically.

Now, gentlemen, a few words in regard to the theory upon which these animal extracts exert these remarkable effects. I have thought a good deal upon the matter and I think I have arrived at something like the truth. But after all a theory, even when supported by indisputble facts, is not a matter of so much importance as the facts themselves. And it is better if you are sure of your facts to have an erroneous theory than none at all. The one I am going to propose is, I think, in accordance with physiological law, and I believe that it will strike your minds as being based on common sense, and as being sufficient to account for the observed phenomena. Briefly stated, it is as follows:

Organic beings possess the power of assimilating from the nutritious matters they absorb, the peculiar pabulum which each organ of the body demands for its development and substance. The brain, for instance, selects that part which it requires; the heart, the material necessary for its growth and preservation, and so on with the liver, the lungs, the muscles, and the various other organs of the body. No mistake is ever committed; the brain never takes liver-nutriment, nor the liver, brain-nutriment; but each selects that which it requires. There are, however, diseased conditions of the various organs in which this power is lost or impaired, and as a consequence disturbance of function, or even death itself, is the result.

Now, if we can obtain the peculiar matter that an organ of the body requires and inject it directly into the blood, we do away with the performance of many vital processes which are accomplished only by the expenditure of a large amount of vital force.

Let us suppose a person suffering from an exhausted brain, the result of excessive brain-work. Three hearty meals are eaten every day; but no matter how judiciously the food may be arranged, the condition continues. Now if we inject into that person's blood a concentrated extract of the brain of a healthy animal we supply at once the pabulum which the organ requires. Then, if under this treatment the morbid symptoms disappear we are justified in concluding that we have successfully aided nature in doing that which unassisted she could not accomplish.

All this is applicable, not only to the brain, but certainly to the heart, the generative system, the spinal cord, and I believe other organs of the body. I have repeatedly seen a feeble heart rendered strong, the blood corpuscles increased in number, and the color of the blood deepened by the use of Cardine, and I have many times seen an exhausted sexual system restored to its normal power by the use of Testine, Cerebrine and Medulline.

Such is the system, and yet I am not quite sure that it is entirely new. I recollect reading nearly forty years ago an account of some observations made by, I think, a German physician, relative to the treatment of diseases of the several organs of the body by a system of diet, consisting of the corresponding organs of healthy animals. Thus, liver-disease was treated by beef's liver, heart-disease by beef's heart, brain-disease by beef's brain, and so

on. My memory seems to be clear on the main point, but I have searched in vain for the paper to which I refer. The fact, however, that the various foods in question were cooked and were taken into the stomach constitutes a great difference with the system which I am now discussing, both physiologically and therapeutically; and the results do not admit of comparison. The germ of the idea, however, is the same, and I cheerfully yield to my unknown proto-observer whatever distinction may be claimed on the score of priority.

And while I have been conducting my observations others have been at work in the same direction, but their investigations do not seem to have led to any very definite results, or to have been systematically carried out. Generally they have been performed with the fresh juice of the organs, and, although at first sight this method would appear to be preferable to any other, experience shows that it is, as I have said, not unattended with danger, and I have certainly ascertained that extracts made with glycerine and pressure, extemporaneously, are absolutely without effect, either physiologically or therapeutically.

And now, gentlemen, I commend this whole subject to your serious attention. I shall leave a quantity of Cerebrine with Dr. Leszinsky for distribution among you. I only ask that you will communicate to me the results of your observations.

COMMUNICATIONS.

POTT'S DISEASE: WITH REPORT OF CASES.*

M. M. EDMONSON, M. D., Dallas, Texas.

This disease was recognized by Hypocrates and Galen and methods for its treatment were divised by Ambrose Pare. In 1783 it was first accurately described by Percival Pott. Since that time much has been written of its causation, symptamatology, pathology and treatment.

As the subject is a broad one I will only attempt to give an outline of the signs and symptoms of the incipient stage, and urge the importance of an early diagnosis and treatment.

The diagnosis of Pott's disease after the deformity occurs is only too apparent and from this point of view demands no further notice. It is before this late stage is reached that the skill of the physician and surgeon is called in to alleviate some obscure pain, and to trace to its origin the disease that causes a derangement of the nervous system that makes itself apparent at some remote point, as in the respiratory or digestive systems.

The result of careless examination and a treating of symptoms without due regard to the cause, is made manifest by a record of cases compiled by Dr. Lewis A Sayre of New York. In his work on Orthopedic Surgery he states, that of 225 cases sent him by physicians, only three were sent before the deformity had occurred, and yet the majority of these cases had been treated for some supposed disease.

After making a careful examination of the different organs, and no organic lesion can be found that will account for the chronic symptoms that exist, the patient should be stripped and the spine thoroughly examined. A rigidity of the muscles of the back will be present in this early stage, which rigidity is "Nature's splint" for holding the spinal column in a fixed position and preventing jars and motions in the affected part. A difference in the temperature of the parts, determined by a delicate surface thermometer, may be of service in locating the disease.

The symptom of most importance, and the first complained of by the patient, will be that of pain due to pressure from inflammation on the spinal nerves as they pass out of the canal at the point of disease. The symptoms resulting from this will be most marked at the peripheral distribution of the

*Read before the North Texas Medical Association, December 14th, 1892.

nerves and consequently will vary according to the vertebræ involved. When the disease is high up in the cervical region the pain is most marked at the back of the neck and over the shoulder. If lower down in this region it may cause a chronic irritable cough, difficulty in swallowing and short, jerky respirations. In the upper dorsal region, pain in the chest and on both sides is a prominent symptom. If the sixth and seventh vertebræ are involved the patient may complain of indigestion, flatulence and the sensation of a constricting band around the body. The nerves of this region have their peripheral distribution directly over the pit of the stomach. If the disease is lower down in the spine, the bladder and the rectum may be involved, with radiating pains down the thighs.

In a large proportion of these cases the disease is situated in the intervertebral cartilages or in the anterior part of the body of the vertebræ, hence the pain is often symmetrical. If the first and second cervical vertebræ are involved, the attendant symptoms may be only on one side, giving the position of wry neck which is often mistaken for an idiopathic torticollis. If lower down in this region, or in the upper dorsal, the attitude of the patient is almost pathognomonic; the head is pushed forward, the chin is raised and the whole spinal column is rigid, due to muscular contraction. Lower down in the dorsal region the shoulders are raised and pushed backward. Still lower down the child leans backward protruding the abdomen. If the lumbar vertebræ are involved, the thigh is often flexed, due to psoas contraction which, on account of the deformity, is sometimes mistaken for morbus coxarius.

The absence of pain on direct pressure is no evidence that the vertebræ are not diseased. If the anterior part of the body is diseased pressure on the spinous processes, crowding them together, will diminish the pressure between the bodies and partly relieve the suffering of the patient. Pressure on the head will invariably increase the pain, while suspension by the head and axilla will relieve it. This, I consider the sign *par excellence* in diagnosing Pott's disease. If the disease is primarily at the junction of the ribs with the vertebræ pressure upon the ribs may be the only means by which you can cause pain.

The treatment of these cases is a very important subject. For not only is the life of the patient involved, but long years of suffering follow if the ravages of the disease has spared life in the deformed, shrunken frame. For these reasons is it not strange that this subject has demanded so much attention. All that has been written on the treatment of Pott's disease has one paramount object in view and that is complete rest to the diseased parts. Every deviation from this state of rest brings with it pain and the admonition that the parts are not in a condition for restoration.

Hilton says that "growth is the autotype of repair prefiguring the capabilities of existing structure to repair themselves. As is seen in the growth of the Animal and Vegetable Kingdoms rest is necessary for their full development. In the Animal Kingdom this is obtained by sleep; with plants it is by the heat of summer or the cold winter; then how much more necessary is rest for diseased parts before they can be fully restored to a healthy state, as growth and repair bear a close relation to physiological rest, both local and general."

With this as the essential condition what has been done to obtain it? The first that would suggest itself would be the recumbent posture as by this method all weight is taken off the diseased vertebræ. Samuel D. Gross advised this as an indispensable condition not to be departed from. Yet this method of treatment has serious objections. As a rule these patients have a tubercular diathesis and in many cases are emaciated, weak and anæmic. Take from them the requisites of good health, exercise, sunlight and fresh air and you have taken away the most valuable adjuncts that nature has given man to preserve and restore health.

This being recognized as a condition second only to rest, methods have been devised whereby both can be obtained. The first adaptation of these principles of treatment was made by Dr. C. H. Taylor, of New York. He constructed a brace which gave an excellent antero-posterior support and allowed the patient to take all the exercise necessary for good health. This brace with some modification was

almost exclusively used for years and splendid results were obtained. It is still used by some orthopedic surgeons in the larger cities where the surgeon can superintend the construction of the brace and any modifications that have to be made, for, unless the brace fits accurately and gives the proper support, it does more harm than good. Thus will be seen the impracticability of this or any other brace that has to be made simply from the measurements of the surgeon. Again its great expense would exclude its use in many cases.

The treatment by means of corsets and jackets has given as good if not more satisfactory results than were obtained by braces. The leather jacket made from a plaster cast of the body is expensive and will in a short time become loose and fail to give the necessary support. Cocking's poro-plastic jacket has the same objections, while the plaster jacket, for its general utility, cannot be excelled.

The plaster jacket owes its origin to Dr. Lewis A. Sayre, and his unqualified recommendation of its use has been fully justified by his successful treatment of cases and by its general use to-day. After suspending the patient by the head and axilla until the most comfortable position is reached, the plaster jacket can be made to fit the form perfectly and to give the necessary support and fixation to the diseased parts. The jacket alone may be sufficient when the disease is situated below the fifth or sixth dorsal vertebræ, but when just above this point the jury-mast must be used in conjunction with it.

In an exhaustive article written by Anders in 1889, on the effect of suspension, he concludes that the result is not a separation of the vertebræ and does not directly affect the projection. Yet if bony anchylosis has not taken place, suspension does in some cases decrease the deformity. This can be determined by actual measurements. While this is not due to an actual separation, yet all weight is taken off the anterior portion of the vertebræ and the spinal column is elongated.

The fact the spinal column can be elongated is made clear by G. Frank Lydston, in an excellent article on the treatment of Locomotor Ataxia. This elongation is due in great part to the elasticity of the ligamentum sub-flava. If this can be done when all the structures are in a healthy state why can it not be done in Pott's disease before consolidation has taken place? Some objections have been made to the plaster jacket on account of its weight, and because, after being worn for some time, it becomes soiled and will break down. The slight weight of the jacket, if it is made of the proper material, is not an objection. The other instead of being an objection should be a recommendation for its use as in three or four months it can be re-applied, holding what we might have gained in a reduction of the deformity, and the new jacket made to fit more accurately every change in the form of the child due to growth.

In conclusion I will report two cases that illustrate these old but ever true principles. I give these cases as one was treated before the deformity had occurred and the other after.

Case I. Frank D., aged two years, family history good, no tubercular diathesis being present. The child was in perfect health until April 1891, when he fell about two feet striking on his back. He complained of great pain and was stiff and sore for a few days. Nothing further was noticed until the following June when he began carrying his head in a peculiar position; the head was pushed forward, the chin raised, the shoulders were drawn upward and backward and the body held rigid. Walking or stooping, he was careful and guarded in all his movements, never allowing the spine to bend. At this time he was restless in his sleep. So long as he was in one position he was quiet, but whenever he would move or attempt to turn over he would cry out. On three or four occasions, when the mother was giving him a bath, she tried to straighten his head. Whenever she attempted this the child became unconscious, his respirations were short and rapid. This is a brief history of the case up to the time I saw him in November, 1891, when I was called in consultation by Dr. H. A. Morley of Dallas. Upon examination we found the condition stated above and these additional signs: That pressure on the head and buttocks crowding the vertebræ together increased the pain, while suspension relieved it and his respiration became full and easy. This convinced me that the child was suffering

from spondilitis. The sixth and seventh cervical vertebræ were involved. I could not apply the plaster jacket at once as his abdomen protruded so much that it was impossible to get a good support from the jacket. On December the 12th, I put him in an improvised cuirass making extension on the head. This answered my purpose for the time being, and the child rapidly improved in general health. On January 17th, about five weeks after treatment was begun, I applied the plaster jacket and jury-mast. This treatment was continued, putting on a new jacket every four months until an absolute cure was effected.

Case II. Maude M., aged fourteen, came to me in April, 1892, and gave the following history: In April, 1888, she fell; was sore and stiff for a few days following, but no definite symptoms resulted at that time. A few months after this a slight prominence was noticed in the middle dorsal region. The family physicians were called in and, recognizing the trouble, advised her to lie in bed for several months. She did this for four months and improved some in general health, but the curvature had increased. Nothing further was done until I saw her last April. As the disease was still progressing and the curvature was very marked I applied a plaster jacket. She improved in general health, and I feel satisfied that the disease is stopped. This is all that I hoped for in this case, as the disease was of long-standing and it was impossible to obtain a recession of the deformity.

RHEUMATISM.*

F. H. RUSSELL, M. D., Bluffdale, Ill.

One of the most frequent as well as most troublesome diseases that the practitioner is called upon to treat in a general practice is rheumatism, muscular and articular. Articular rheumatism may be divided according to its stage of persistence into chronic and acute. Some writers make a third division into the subacute, but I think nearly if not all of the characteristics of articular rheumatism may be described under the heads of acute and chronic stages. When the fever is high, accompanied with local pain and swelling, it is called acute rheumatism or rheumatic fever. Cases presenting local pain, stiffness, impairment of locomotion and persisting a long time, but without fever, are called chronic rheumatism.

Bartholow says there are three types of bodily conformation in rheumatism. *First*, the pale and anæmic. *Second*, the robust and vigorous with an inherited tendency. *Third*, the obese, often given to the consumption of malt liquor and having an acid form of indigestion. The three types are named in the order of their frequency.

Rheumatism is, generally speaking, a disease of youth and early manhood. It rarely commences before the seventh or after the fiftieth year. This rule is far from invariable, for there are cases on record commencing in the first year of infantile life. Rheumatism is more frequent in males than females. Not because men are more susceptible to it than women, but because they are more exposed to the causes producing it. It is rare that we have an opportunity of studying the post-mortem appearances of rheumatism, but when they have been studied the morbid appearances are slight compared with the apparent extent of the mischief. Blood when drawn coagulates rapidly and contains an excess of fibrin. The excess of fibrin sometimes amounts to ten per cent. The articular cartilages are œdematous. The synovial fluid is increased in amount and changed in character. Instead of being an homogenous transparent viscid fluid, it is thin, watery, reddish from extravasated blood, and turbid from the presence of fibrin and pus corpuscles. There is never any considerable amount of blood in the fluid except in patients of a hemorrhagic diathesis. The color of the fluid varies according to the amount of extravasation. Its reaction is alkaline. Albumin and fibrin are found

*Read before the Medical and Surgical Society of Western Illinois, January 13, 1893.

in abundance. Urate of soda is never found. Oedema and hyperæmia of the endocardium and pericardium are local manifestations of a constitutional disease.

The causes of rheumatism are predisposing and exciting. The predisposing causes are, *first,* the inherited tendency. *Second,* Dr. Davis claims long continued physical and mental exertion. *Third,* anything that retards excretion and secretion. *Fourth,* season of the year, as most of the cases occur between December and March. *Fifth,* insufficient or poor quality of food and clothing. *Sixth,* pregnancy and prolonged lactation. *Seventh,* scrofula, phthisis and cancerous affections frequently precede rheumatism. The principal exciting cause is exposure to cold and dampness thus suddenly arresting excretions.

Dr. Loomis claims that excess of sulphur sometimes causes rheumatism, but the most universally accepted theory is that rheumatism is caused by excess of lactic acid in the blood. This has been clinically proven by the fact that patients taking lactic aid for the cure of gout are affected subsequently with rheumatism. It has been proven experimentally by Richardson by injecting lactic acid in the veins of a cat, rheumatism being developed within twenty-four hours. One attack predisposes to another. Articular rheumatism generally comes on suddenly in the night, and with little premonitory symptoms. It is generally ushered in with a chill or chilly sensation; a feeling of general *malaise* with pain, heat and swelling of one or more joints. The initial chill is followed by fever running from 102° to 104°. The patient has thirst, anorexia, a coated tongue, constipation, headache, wakefulness and general uneasiness. At first the large joints are attacked, but subsequently the small ones may be involved. The termination of the febrile symptoms is gradual and not by crisis. The pulse is slower than the temperature would indicate, rarely running above 95. There is generally profuse acid perspiration. Pain is aggravated by motion, and is most apparent in joints not covered by adipose tissue, as the elbows and knees. The urine is scanty, strongly acid, deep-red in color and deposits a great quantity of urates and uric acid. The chlorides are diminished and the sulphates increased. Albumen is present in small quantities. The saliva is said to become acid in reaction. Delirium is sometimes present in severe cases. It is always accompanied with high fever, and sometimes the temperature reaches 109° to 111°. Generally the local symptoms follow the law of parallelism, that is, parallel joints are affected simultaneously—as both elbows, both knees, etc.

In the diagnosis of rheumatism we have to differentiate from pyæmia; the history of the case, the recurrence of chills, and multiple abscesses are diagnostic points and ought to prevent this error. We have to differentiate from gout, but the fact that the small joints are attacked first in gout and last in rheumatism, and that gout is a rare disease in this country and has a history of high living, ought to prevent this mistake. Rheumatism is a disease of early life; gout rarely occurs before the age of thirty-five. Also in gout cutaneous affections are frequent; they are rare in rheumatism. We have to differentiate from arthritis deformans. Here, as in gout, the small joints are attacked first. Arthritis, unlike rheumatism, attacks women more frequently than men. In arthritis there is no fever even in the acute stage. This is a diagnostic point. In rheumatism the local manifestations move from joint to joint; in arthritis they are stationary.

Before closing my remarks on the diagnosis of rheumatism I will call your attention to a disease that we have to differentiate from and that the text-books do not put much stress on, namely, morbus coxarius. I saw one case of morbus coxarius treated for over a year for rheumatism, and have always thought that if the diagnosis had been made sooner the result might have been different, for the patient was a girl and was left a cripple for life. The diagnostic points are: Rheumatism is a disease of early manhood, while morbus coxarius rarely occurs after twelve years of age. In rheumatism the local manifestations are migratory; while in morbus coxarius they are stationary in the hip-joint. Motion is embarrassed in morbus coxarius; not so much so in rheumatism. Rigidity of the muscles about the hip and inability to rest the weight of the body on the affected limb are diagnostic points. Morbus coxarius is always unilateral; rheumatism rarely so. In coxalgia there is no initial chill and but

slight, if any, fever. The psoas iliacus and adductor muscles are in an unusual state of tension, hence the thighs are flexed and foot everted. These are diagnostic points that ought to prevent mistake.

The prognosis of rheumatism is generally good. The mortality is estimated at three per cent. Rheumatism runs an indefinite course. The milder the attack the shorter the duration. The great danger in rheumatism is heart complications. The younger the patient the more liable he is to these complications. Various estimates have been made as to the frequency of heart complications. Some authorities put it at five per cent., others as high as seventy-five per cent. A strange sequelæ of rheumatism sometimes is chorea.

In the treatment of rheumatism there are a great many remedies to choose from. Each authority has a different notion as to how it should be treated. I think different cases require different treatment; but in all cases there are certain indications to meet: *First*, to neutralize the acid that is supposed to cause the trouble. This is done in two different ways, either by the alkaline or the acid treatment. By the alkaline treatment we should give the alkalies, preferably the soda salts until the urine is distinctly alkaline. In the acid treatment we use either the salicylic acid or its salts. The way the acids are supposed to work is by having a stronger affinity for the blood than lactic acid. The blood gives up its lactic acid and appropriates the salicylic acid. The *second* indication is to relieve pain. This is done by opiates, or is sometimes accomplished with antifebrin, but this remedy is not to be pushed too far for it is very depressing. Phenacetine is an excellent remedy in some cases for the relief of the characteristic pains of rheumatism. The *third* indication is to prevent heart complications. To meet this indication the universal verdict is in favor of the ammonia salts, especially the bromide and carbonate. The *fourth* indication is to repair damages and prevent recurrence. To do this keep the secretions and excretions in good working order. To accomplish this, attention must be paid to the skin, kidneys and bowels. To meet this indication the so-called alteratives come into play. There is one remedy in the alterative group that I wish to call especial attention to in the treatment of this disease. It is poke root or phytollacca. I have seen its beneficial effects so often demonstrated as to leave no doubt in my mind that it is a remedy of extraordinary power in rheumatism, especially in the chronic form.

In the weak and anæmic, tincture of the chloride of iron is excellent. Arsenic and potassium iodide are frequently beneficial in chronic rheumatism. Salol is a remedy of remarkable virtue in this disease. In the experimental work that is going on in the coal tar products, there is no doubt but some time we will have rheumatism as completely under our control as an ordinary intermittent fever.

Good Cause for Suicide.

William Harman, a resident of Titusville, Pa., committed suicide a few days ago from a melancholy conviction that he was his own grandfather. Here is a singular letter that he left: "I married a widow who had a grown-up daughter. My father visited our house very often, fell in love with my step daughter and married her. So my father became my son-in-law and my stepdaughter my mother, because she was my father's wife. Some time afterwards my wife had a son; he was my father's brother-in-law and my uncle, for he was the brother of my stepmother. My father's wife—i. e., my stepdaughter—had also a son; he was, of course, my brother, and in the meantime my grandchild, for he was the son of my daughter. My wife was my grandmother, because she was my mother's mother. I was my wife's husband and grandchild at the same time. And as the husband of a person's grandmother is his grandfather, I was my own grandfather." —*Ex.*

They Would Declare the Corpse Dead.

The court of Schleswig-Holstein recently issued the following curious notice: "At the request of Herr Peter Lobmann, of Altona, the seaman Dietrich Lobmann, who was born in Kirchmoor in November, 1848, and was drowned on the journey from Stockton to Hamburg while sailing in the ship Bertha Jenny, is hereby called upon to appear before this court and report himself, on or before Friday, January 20, 1893, at 11 o'clock P. M., under pain of being declared dead."—*Ex.*

SOCIETY REPORTS.

THE MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting of Januany 6th, 1893.

THE PRESIDENT, Dr. F. C. Simpson, in the Chair.

EPITHELIOMA: TRAUMATIC EPILEPSY.

DR. W. O. ROBERTS: About the first of October a man fifty-five years of age, German, had his forearm amputated at the University Clinic, for removal of an epithelioma of the hand. Last Tuesday he appeared at the clinic again with a tumor in the axilla on the same side. This morning I removed the growth, cleaning out the axilla thoroughly, leaving nothing except the blood vessels and nerves. I not only removed the tumor, fascia and fat from the axilla, but also the skin which was adherent to the growth. The tumor extended from the floor of the axilla to the apex.

No. 2. There was also at the clinic a man twenty-eight years of age, who, thirteen years ago, was struck on the side of his head with a hoe. A few months after the healing of the wound he began to have dizzy spells and shortly afterward regular epileptic convulsions. The cicatrix left from the wound was exceedingly sensitive and pressure upon the cicatrix he claimed gave him a peculiar sensation in the head. Thinking that possibly this was a case of epilepsy due to imprisonment of a nerve in the cicatrix I removed it and examined carefully for evidence of injury to the bone, but could not discover any. There have been such cases reported. I saw not a great while ago in one of the journals a report of a case where epilepsy was relieved by removal of the cicatricial tissue from a wound of the scalp. I do not take much stock in the theory, still as they have been reported I think that we ought to give these cases the benefit of the doubt and do the operation.

DISCUSSION.

DR. W. L. RODMAN: I saw this patient when he first came to the Clinic in the month of October, for amputation of the hand, and was very much surprised to see him to-day, in the condition that he was, with all of this enlargement beneath and in the axillary space. It seemed to be a case of epithelioma and, from the general condition of the patient at the time, it looked as if it was a very favorable one for operation, and as if he possibly would be relieved for several years as a result of the amputation. The question will naturally come up as to whether these glands were enlarged at the time of the amputation, as it has been such a short time since the operation, but I am pretty well satisfied in my own mind that the glands were not enlarged at the time amputation was done. I made a careful examination at the time and no enlargements could be detected. This was also done by Drs. Yandell and Roberts who performed the operation. The man was very fleshy and possibly there may have been enlarged glands which could not be detected. It is a very interesting and unusual case and teaches us that epithelioma, which we are usually inclined to look upon as the least malignant of all forms of carcinoma—and undoubtedly it is the least malignant save atrophic scirrhus—sometimes runs as rapid and malignant a course as encephaloid. I have no doubt this man will be dead in less than six months. He suffered a twelve-month before operation. Eighteen months is a rapid course for epithelioma in any situation.

As to the second case, I fully agree with Dr. Roberts in the statements he makes. I have seen a great many operations for epilepsy and have never yet seen a single case where the patient was permanently benefitted thereby. There is sometimes relief for a short period as a result of trephining, but in all cases that have come under my observation the paroxysms have returned in less than six months after the operation.

DR. TURNER ANDERSON: From the appearance of the tumor exhibited by Dr. Roberts it seems to me the operation must have been a very thorough one.

DR. W. O. ROBERTS: I simply want to say that I never examined the patient

from whom this tumor was removed, prior to the operation, except last Tuesday, but I know that he was thoroughly examined and as Dr. Rodman says no enlarged glands were detected. He was an exceedingly fat man and, of course, if these glands were located high up in the axilla they would not have been detected. Very frequently in carcinoma of the breast we are unable to detect enlargement of the axillary glands, unless they are of considerable size, until after the axilla has been opened and thoroughly explored, then we wonder why we were not able to detect them before operation. We do have cases of epithelioma followed by encephaloid and the rule is after removal of a malignant growth—it matters not what form of cancer it may be primarily, whether it be epithelioma, scirrhus, or otherwise—the recurrent growths are apt to be encephaloid in character and to be very rapid in their development.

I saw a case not long ago, of a man forty years of age, who had what was supposed to be sciatica, and for this he was treated several weeks. Then there was a change made in his medical attendant and the second doctor discovered a lot of growths about the size of an almond on one of the patient's legs; two or three located between the knee and ankle, one just above the knee, one about the centre of the thigh on the outside of the leg and one in the gluteal region—all on the same side. These growths were exceedingly sensitive to the touch and the man suffered intense pain. At the time I first saw him, about two weeks ago, the growths were very sensitive, and, in addition to those I have mentioned, there were two or three others in the gluteal region. I told the doctor that I was under the impression that these growth were multiple sarcoma, possibly involving the branches of the nerves which caused them to be so exceedingly painful. I saw the man again two or three days ago and several more of these growths had appeared in the gluteal region and one on the tuberiosity of the ischium on that side. We decided to remove one of these growth for the purpose of microscopical examination and I selected the one on the outer side of the thigh; it seemed quite movable and quite hard. I cut down upon it and found it in the body of the vastus externus muscle and soft; it came out in pieces; just as soon as I cut through the muscle it welled out like a broken down neoplasm. From the appearance of the growth I suspected sarcoma; analysis has not yet been made; it was only removed yesterday.

Dr. W. L. Rodman: Do you think these tumors have grown any in the last two weeks? And how long has the patient had them?

Dr. W. O. Roberts: They do not seem to have increased much in size, but have considerably increased in number. I believe they have all appeared within the last eight weeks. There are certain muscles of the leg which are especially liable to sarcomatous deposits. These, if I remember correctly are: the pectineus, sartorius and gluteus muscles. The growth I removed, however, was in the vastus externus. As I say microscopical examination has not yet been made of the growth removed.

Dr. W. L. Rodman: Rare as sarcomas of muscles are, I think that you have such a case. Butlin reports only twenty-one such cases in his work upon malignant disease.

VARICOCELE.

Dr. T. L. McDermott: In assuming the discussion of varicocele, a seemingly surgical subject, some explanation might be proper upon its introduction by a general practitioner. In these, as well as numerous other distinctly operative cases, however, he is the person first consulted and upon his judgment and decision largely depends the final measure adopted for relief. So that the question becomes of paramount importance to the interests of the patient and diverse to those of him intrusted with his management.

The hypochondriasis that accentuates its intensity and in fact first leads the victim to solicit assistance, becomes and remains the leading symptom to invite diagnosis and prompt redress. Such being the case, is it not natural to premise that it opens to the general practitioner a tempting avenue to the administration of treatment for restoring a depleted function, which may require a local surveillance instead of a general cure?

The surgical authorities themselves, are at very wide variance upon the advisability of operative procedure, many contending the interference to be useless and even blameful, others, more sanguine, only op-

erating to relieve the incumbent tension and consequent pain. It becomes then a mooted question whether it is entirely proper or magnanimous for the physician to yield up a patient at the expense frequently of personal vanity and always of pecuniary loss.

The literature of the subject, so far as text books go, is very obscure, and its disquisition entirely inadequate to the magnitude of the issues concerned. Its utility, however, is a matter of unbounded importance, possibly, to the individual concerned, second only to existence itself.

The various morbid conditions of mental deterioration that have found their origin in this, as well as other morbific sequelæ of a sexual impairment, which saps not only the well being but the highest intelligence of pleasurable emotion known to human indulgence, certainly appeals to every scientific endeavor that might encompass its fullest fruition. This phase of the subject is the suggestion of its discussion prompted, in this instance, by a letter from a patient who had recently submitted to the operation with the most gratifying results. In this instance there came to consult me, a bridegroom of a week, on his wedding tour—asking advice and medicines for the restoration of an incompetency which he attributed to early indiscretions. He was utterly disconsolate over his fruitless efforts to accomplish the marital act, and a prey to remorse intense enough to lead him possibly to some desperate rashness. Upon examination I found a varicocele and divining the trouble, advised an operation. It was performed at once, and as I have said before, with the most rapturous success. I shall read his letter written a few months later:

Dr. W. L. Rodman, Louisville, Ky.

Dear Doctor:—Allow me to thank you for your kindness to me, and for the successful manner in which you treated my case. I am entirely well and feel better than for twenty years past. I have gained seven pounds since I came home and my wife seems perfectly happy.

Imagine drowned honor dragged up by its matted locks from any slough of despond you could conjure, and any other simile of tragic lore, but what is the comparison with this belted knight of Venus, springing from the depth of despair, thrice armed and eager for the fray. How different the scene since that bridal morn. The church bell changed its funereal dirge to pæon strains and frisking birds piped roundelays from bush and dell, to greet the gallant groom as he drew near home.

I have another letter from another subject, which I shall also read, bearing the same burden in its tenor and filled with praise:

Dr. W. L. Rodman, Louisville, Ky.

Dear Doctor:—Referring to the operation performed on me for varicocele, will state that I have been much benefitted, as I feel that it is impossible to copulate enough at times. Prior to operation I was passionate at times only, but now I believe I can raise a stake at any time. I feel very much better and stronger since the operation, and am sorry I did not have the work done sooner.

It is useless for me to discuss the causes of varicocele, as they are necessarily obscure. I could only suggest that varicosity might be an idiosyncrasy, as we meet it in individuals of all ages, of good or bad habits, and, in both the symmetrical and ill-formed. This obtains in the limbs as well as scrotum. One peculiarity, however, is evidently due to anatomical configuration, namely, that the seat of varicocele is usually found on the left side. This is due to the spermatic vein emptying into the renal vein instead of the vena cava on that side.

Of the operations, the open dissection of the veins is certainly preferable, in my experience, to Lee's, in which the vein is ligated. Under antisepsis it is almost absolutely safe, and gives little detention even from business affairs.

In a resume of the cases that have come under my observation I incline, strongly to the opinion that, in suitable cases when the testicle is losing its resiliency and becomes softened, the operation should be performed, not only to relieve the distress incident to its dragging weight upon the cord, but also to restore to a lost impulse the franchise of love.

DISCUSSION.

Dr. W. L. Rodman: There has ever been a wide diversity of opinion among medical men as to the causation, pathology and treatment of varicocele. The causation of the disease is usually ascribed, as Dr. McDermott says, to the fact that the spermatic veins on the left side embogue into the left renal vein at a right angle, instead of into the vena cava at an acute angle, as they do upon the right side. This demonstration was first made years ago by my distinguished friend Professor Brinton, of Jefferson College. This anatomical point has not been satisfactory

to all, and there have been many other reasons advanced for the fact that varicocele is so much more common upon the left than the right side. Some claim that it is due to an accumulation of fecal matter in the sigmoid flexure, whereby pressure is made upon the spermatic veins and the return of venous blood prevented. McGraw, a prominent surgeon of Detroit, Mich., read a very interesting paper upon this subject at the last meeting of the American Medical Association, in which he assigned as a cause of varicocele the action of the cremaster muscle. This I do not believe will hold good, as it does not explain the greater frequency of the disease upon the left side. Others have ascribed the occurrence of varicocele to early excesses, etc., etc.

However much we may differ as to the causes of varicocele, there should not be such a contrariety of opinion as to its proper treatment. Many authors do not take a pronounced stand in favor of treating variocele surgically. To me nothing more imperatively calls for operation than an aggravated case of varicocele. Moullin, one of the most recent authors has very pessimistic views upon the subject, and only advises operation in the most extreme cases where there is disintegration of the testicle.

He also greatly magnifies the danger from operation. His personal experience must be limited. I believe there are very few varicocele of any size, which last for five or six years, where there is not a considerably injury done the testicle, and when this can be prevented by so simple and safe an operation, it seems to me that it should be done more frequently than it is. I can very well understand how the older authors argued against operations for varicocele because none of the operations practiced prior to the last five or ten years were an approach to the ideal. Subcutaneous surgery is surgery in the dark. I did very few operations for varicocele until within the last five years, since that time I have done quite a number or them; in the last year I have performed I think on an average about one per month. I feel that it is at times one of the most humane and considerate operations that can be done. Wherever I find there is a well marked swelling or tumor caused by enlarged veins, where I find pain or dragging of the testicle, where there are lumbar pains, etc., whether accompanied by any grave cerebral symptoms or not, I advise early operation. If a man has a simple varicocele and has never worn a suspensory bandage, especially if he be a young subject, I advise him to try a bandage for six months or a year and then, if there is no improvement, I urge operation. Only a few days ago I declined to operate upon a young married man telling him to procure a suspensory bandage and wear it for a year, then if he received no benefit to come to me again and I would operate.

I want to give you the history of the first case referred to by Dr. McDermott: He was a man about thirty-seven years of age, and as the Doctor has stated, he came to his office about a week after he was married. He was referred to me, and when he came to my office I noticed his actions were very peculiar; he came into the room and was very particular to close the door carefully and afterward to look around to be sure that there was no one present; he then slipped up to me and in an undertone remarked: "Doctor, I am a victim." I asked "a victim of what?" To which he replied, "Early excesses." He then said that he had been to see Doctor McDermott who had made an examination and told him that he had a varicocele and advised his consulting me. I made a careful examination and saw that this was a very extreme case. I have seen very few cases where there were such marked mental symptoms, and where there was such prompt and thorough relief by simple operation. He also told me that he had attempted intercourse twice since marriage and had utterly failed; that he was unable to get an erection, but had had one imperfect emission. I sent him to the infirmary and operated the next morning. I told him when he left not to attempt intercourse until the third week after the operation. I did not hear of him until about a month afterward when he came into my office one day, and I never saw greater change in a man's appearance in my life; the first thing he said was, "Doctor, I am all right." I asked him more particularly what he meant by being all right, and he said that he had no trouble and could have intercourse as well as he ever could in his life. I inquired as to the frequency with which he could perform the marital act, and he replied two or three times per week. He had then

been married about two months. We afterward received a letter from him which was read by Dr. McDermott, confirming the assurances he gave in person that he was entirely relieved. The results in this case are certainly very gratifying, and I feel safe in saying that no treatment by electricity or any other means could have brought about the same relief as by operative procedure. In all the cases I have operated upon for Dr. McDermott in the last six or seven years, four of which have occurred in the past year, I can conscientiously say, and he will bear me out in the statement, there has not been a single one of them that has not been entirely relieved. They have not only presented the appearance to me of being relieved, but each one has assured me that he felt perfectly well in every respect. I do not know that I have ever done a varicocele operation where the results were not all that could be expected. In certainly twenty or thirty operations of this character that I have performed in the last two years, I only call to mind one case where the patient claimed that he was not relieved, and yet all the facts in the case tend to prove that he was entirely cured. Three or four years ago a young man was brought to me by a physician of Lawrenceburg, with a varicocele on the left side. I operated upon him at the St. Joseph's Infirmary, and he remained there about two weeks. I thought he was entirely relieved of the trouble; in fact he said so himself. He went home and I heard nothing more from him until I sent him my bill, which he declined to pay, stating that he had not been cured and for that reason refused to pay the bill. However, I learned through his physician, who examined him, that he was entirely cured, and I am certain that he was. He married, which is a confirmation of it, in less than six months after the operation, and has two children now. I believe that the modern operation of excision, removal of about an inch of the veins and suturing the stumps together accurately so as to lift the testicle up, is the ideal operation. And I cannot agree that there is any danger in it, as some authorities would have it appear, as I have never in my own experience seen a single untoward symptom. I have only seen one case of orchitis following varicocele operation and that was in one of my earlier operations. As I have said no unfavorable symptom has occurred since I have practiced the open method as described above. I rarely see suppuration. I prefer iron-dyed silk for suturing the veins.

Dr. T. S. Bullock: I have enjoyed Dr. McDermott's paper very much, and can testify to the extreme nature and frequency of this trouble. I would like to say a word or two in regard to the causation: I have always thought varicocele in part was due to the frequent excitement of sexual sentiment without gratification. I believe that there are very few young men who remain unmarried for any great length of time, and have not unusual facilities for sexual pleasures, that escape without varicocele.

Dr. W. O. Roberts: I have very little to add to what has already been said with reference to this subject. Varicocele is an exceedingly common affection, and it occurs in the young as well as the old. There is no doubt that in young subjects the disease sometimes passes away under appropriate treatment; after adult age, however, I do not believe that it ever goes away. As to the cause of the disease, it has been attributed, as Dr. Rodman says, to quite a number of things. It rarely ever occurs on the right side. I notice that in Agnew's examination of thirty thousand troops he never discovered a well marked case on the right side. Cooper, Marshall and others also report not having found a single well marked case on the right side. It does, however, sometimes occur, and occasionally in the same subject on both sides. I have, during the past three months, had a case of this kind in which I operated first on the left side and two months after operated on the right side. As to the indications for operation—I think that we are justified in advising it when we find cases of varicocele of long-standing, where there is evidence of wasting of the testicle, where the patient suffers from dragging pains in the loins, and where we want to operate for the purpose of relieving the mental condition which it gives rise to in a great many instances. There are many cases, however, of large varicocele in men who understand it, you might say who are not frightened by it, where it does not seem to affect their virile power in the least. Still in these cases, where there is evidence of wasting of the testicle, I think operation should be advised.

As to the different methods of perform-

ing the operation, between the subcutaneous and the open method, I strongly favor the open method. I have done every operation that has ever been advised for varicocele, excepting one, viz: the removal of a large section of the scrotum for the purpose of making a natural suspensory. In former years I did, as Dr. Rodman says he has done, the subcutaneous operation. I have long since, however, given it up. In these cases I find that the patient very frequently suffers from a neuralgic condition of the cord, which continues for months and months. I have seen follow these operations abscesses which, of course, must have been due to want of proper aseptic precautions. The open method I think is decidedly the safer procedure. It is an exceedingly simple operation, and is one which can be done under anæsthesia; the others cannot. When subcutaneous ligatures are applied, you want to have the veins distended so that you can discover them. In doing this operation I make a free incision over the cord and expose the veins. I always remove a large section of the veins, an inch or more, and then bring the stumps together. The method mentioned by Dr. Rodman is an excellent one. After ligation of the veins above and below the central portion is removed, then the ends are brought together and stitched, which brings the testicle well up. I have performed the operation in this way a number of times with the most happy results. Recently I have been following the method advised in *The American Text Book of Surgery*, which is as follows: The veins are exposed but not separated from the fascia surrounding them and holding them together; the vas with its venous plexus is recognized and avoided. An aneurysm needle threaded with catgut is then passed under the vein at the upper end of the incision and again at the lower end; the ligatures are tied and in each instance left with one long end, the intermediate portion of the veins is then cut out with scissors and the stumps are brought into apposition and held by tying the ligature together. This method like that of stitching the stumps together, raises the testis to a higher level and results in shortening the scrotum on that side.

Since I adopted the open method of treatment for varicocele, I have met with only one case in which I had any trouble. That case was in a dissipated man, and the varicose veins and scrotum were very large and the testicle very small. Following the operation there was suppuration and, while it was not excessive, it continued for some little time; but there was no sloughing noticed and the man finally got well. I saw nothing more of him for a year; he came into my office the other day and asked me to examine him; I did so and found that the testicle on that side was gone entirely.

Dr. Turner Anderson: I would like to inquire how the circulation is kept up after removal of a portion of these veins; I should think there would be great danger of atrophy of the testicle.

Dr. W. L. Rodman: I fully agree with what Dr. Roberts has said in regard to double varicocele, and was a little surprised to hear him quote Agnew as having stated that there was not a single case occurring on the right side. I have seen two cases of double varicocele in the last six months. The man who wrote the first letter read by Dr. McDermott had a very small varicocele on the right side, but it was not operated upon owing to its size, and it was evidently the one on the left side that was giving him the most trouble. I operated upon a man at the city hospital about three months ago who also had double varicocele, and I do not think it is as uncommon as has been reported. Another point that might be mentioned in this connection is that men with varicocele are not accepted either in the Army or Navy. One reason why the modern operation for varicocele is so much better than the old subcutaneous method is, that in the subcutaneous operation you can never tell just exactly what structures you are embracing in the ligature, but with the open method you can see just what you are doing.

Dr. Anderson's question is very easily answered. It is only the the superficial veins that are enlarged in varicocele, and there are a number of smaller veins that are situated deeper, that are sufficient to carry on the circulation. That these deeper veins are sufficient to carry on the circulation is shown by the fact that they may so enlarge as to necessitate a second operation. In the ordinary operation only the superficial veins or "pampiniform plexus" are removed. Relapses are rare.

Dr. T. L. McDermott: In all these cases that I have had with Dr. Rodman, I have noticed that the testicle was always smaller on the side on which the varicocele occurred; the testicle seeming to be very much shrunken, in some cases exceedingly so. I think the operation clearly justifiable when such happy results can be accomplished as those stated in the paper read this evening. There is very little information in the text books concerning operations for this trouble, and I believe if more were known of the benefits to be derived from so simple an operation, if people would look into it more, the operation would meet with more general favor.

CORRESPONDENCE.

NEW YORK LETTER.*

About four months ago the New York Academy of Medicine appointed a committee consisting of Drs. Janeway, Jacobi, Prudden, A. L. Loomis, Hamilton, Stephen Smith and R. H. Derby for the purpose of investigating the condition of New York quarantine as well as to ascertain the desirability of establishing a National quarantine. This committee represents the brainiest medical men in the city, and their decision is accepted as conclusive by the mass of New York practitioners.

At a special meeting held at the Academy last week the committee reported the result of its investigations. The members found the quarantine system of this port in a condition wholly incompetent to efficiently protect the citizens against infection from cholera, and that what facilities did exist in the way of extirpating the dread disease, were not satisfactorily utilized by the officers in charge. The members of the committee fear that unless a radical change is immediately made in the quarantine affairs of this port cholera will obtain a foot-hold in our city in the spring. They urged the necessity of the establishment of a National quarantine as the best way to solve the ominous question; claiming that in a National quarantine there would be uniformity and system; international aid would be obtained through our consuls; that well-trained men and better material would be more easily obtained, and that local politicians not unwilling to sacrifice public health to personal emolument would be replaced by men of ability and honor.

The committee regarded the scenes of last autumn a disgrace to the city and could see no way in which a similar scene would not be repeated in the spring other than by the establishment of a National quarantine. The report is a lengthy and scholarly article and if Congress attend to the matter in the way recommended by these famous physicians it is highly probable that Asiatic cholera will not obtain a foot-hold in New York.

***

In a recent lecture, Dr. H. M. Biggs, Professor of Materia Medica at the Bellevue Medical College, reported the results of observations taken during a four week's stay at Carlsbad last summer. He said that although Carlsbad was undoubtedly the most popular health resort in the world, it did not owe its fame to any peculiar constituents of the much lauded waters.

He found that about forty thousand patients go there annually and take a course of treatment lasting from four to six weeks. The most prominent diseases found among the patients are gout, rheumatism, gastro-intestinal catarrh from alcoholism or over-feeding, and disease of the liver and kidneys. An examination of the Carlsbad water showed that it owed its efficacy to sulphate of soda, of which it contains a large amount, sulphate of magnesia, sodium chloride, alkaline carbonates and carbonic acid gas in solution. The main part of the treatment consists in the regulation of the diet and habits, and upon this feature of the course the success of Carlsbad depends. The waters are taken early in the morning, from six to eight o'clock. As many

*Special Correspondent to The Medical and Surgical Reporter.

as four thousand people may be seen walking in the vicinity of the springs. The water is taken, a small glass at a time, every fifteen minutes, the patient meanwhile taking moderate exercise, and this drinking is kept up for two hours. After the last drink the patient walks steadily for an hour or more, the time depending on his strength. After a few days at the resort this exercise can be easily taken without the desire for food or rest. About nine the patient returns to his hotel for breakfast having had nothing to eat before this time. Breakfast consists of a cup of coffee, a roll and a couple of soft boiled eggs. For dinner is served one vegetable, soup, a small piece of roast meat and a half pint bottle of Bohemian red wine. During the afternoon the patient drinks more water from the springs and takes more exercise. Supper at six consists of a cup of tea, a small piece of roast beef, one vegetable and perhaps a little oat meal. All pastry, sugar, salads and fruits of all kind are entirely shut off from the patient. All patients must retire at nine o'clock.

The results of this plan of treatment is often striking. Better results in cases of diabetes are obtained here than in any place in the world. Excellent results are obtained in patients suffering from gastro-intestinal disorders. Many people with gouty, diabetic, or lithemic diatheses visit the spring and take a course every year. Their symptoms are so improved that they were enabled to lead their customary sedentary life the rest of the year.

Professor Biggs is a close observer and made thorough examinations, and it is his belief that there is no peculiar efficacy in the water of the Carlsbad springs; that the medical properties of the mineral waters found at most of the health resorts in this country are equally potent to those found in the Carlsbad waters; that the good results obtained come mostly from the restricted and simple diet, the exercise, the freedom from care and the cessation of injurious habits. The only features peculiar to Carlsbad are the traditions which attend it and the large number of people who go there.

THE ADVANCE GUARD.

Editor Med. and Surg. Reporter:

In the pending discussion between those who assume to represent conservatism and radicalism, respectively, the idea that there can be any middle ground on the subject, or any other than that represented by the extremes, seems to be lost sight of entirely.

It is assumed that conservatives are always conservative, and that so-called radicals are always radical, which idea works great injury to the progress of medical science. But if you accept that part of the definition for conservatism given in the issue of December 24th, which refers to preserving from innovation we will take radicalism every time. To quote again from your correspondent whom, for the sake of brevity, I will refer to as "Conservative." He says "the conservative is the fellow who wants to know before he acts." To reach which point of vantage one must indeed be a very Solon or phenomenon of learning, or else must manifest a large part of his time a position of imposing masterly inactivity. Which latter quality I once heard a prominent and elderly professional man speak of as one of great importance in professional life. Again, "the conservative is the man who has not only seen many theories die out, old treatment set aside, but new theories wither, new treatment fizzle, etc."

I must say, as much as we all deprecate unguarded and irresponsible action in any profession or science, yet does not any one respect an enthusiast more, who occasionally goes wrong, than the man or woman who stands by "masterly inactive" waiting for somebody else to work out the problems of life and science, and then appropriates the results of their successes and failures to his own great and wondrous credit, vaunting himself as one who is always right because he has not enterprise to go either right or wrong upon his own responsibility?

Are the causes of life and death so sacred and inviolable that they shall not be followed to the inner sanctuary?

Is it proved that the men who represent the so-called radicals in surgery—the men who have done more to advance surgery

in the past ten years than the efforts of previous centuries—are any the less impressed with the sacredness of life or the responsibility of their work? On the contrary it is they who carry the responsibility of almost the whole profession. Their load is such as the dull expectant never dreams of, and for reward they often get only obloquy and abuse. Every man who is not content with watching old theories die out, old treatment set aside, is looked on with suspicion and is considered a rampant radical, quack, or, as a climax to all injurious epithets, he is branded as a *specialist* which is supposed to fill the measure of all opprobious terms. And this, notwithstanding the fact that almost every advance of any importance in surgery or medicine, has been a radical step away from some preconceived conservative notion. Medical science originally was a system of baseless theories, bolstered up with specious reasoning and unintelligible vocabulary.

The day is at hand, and even now is, when in place of that we shall have an exact science and a intelligible reason for all things.

And the more specialists we have—be they chemists, physiologists, pathologists or surgeons, by whatever name they are known, be they German, English, French, or American—the better. And, however, many hobbies they may ride, one with his *baccillus tuberculosis* and it antidote *tuberculin*; another with his experiments in hydrophobia and anthrax; another with his listerism and antisepsis, the better for the ultimate result. There is some good in all of them. Because, whatever the ultimate result may be, their reasoning does not start from baseless assumptions, and through patient and arduous laboratory work performed not for selfish ends do they accumulate useful information, which, as was said before, is often appropriated by idle beings, who at one time were ready to abuse and accuse of lying, hypocrisy and simplicity those who, at the expense of much time, labor and pains, have contributed to their stores.

All honor to the searchers after truth in whatever line or direction it may be. And all honor to our American surgeons and practisers of the art of healing for they lead the world at this present day. And their position is not one gained by contentedly standing in the old ranks, pouring over ponderous tomes and argumentative discourses, but by each and every one jostling his fellows, striving for the front rank and to keep at the head of the profession.

As one of our Philadelphia confreres has so aptly said: "It is not so much a ponderous dignity and sick room air that we need, but to know what to do, when to do it and how to do it."

The time has gone by for much abstract theorizing in medical science, but we recognize more and more material agencies, material causes and more and more ought we to get mathematical results. The study of medicine is largely the study of materialism, and that is said to be the reason so many of its votaries become materialists, but such a result is not natural and to the right thinking person the more one studies materialism in the human body the more ought he to grow in spiritual faith.

Rational Treatment of Puerperal Septic Infection.

Dr. J. L. Rothrock (*Northwestern Lancet*) says:

Puerperal infection is caused by two widely different groups of bacteria, which must be distinguished since they necessitate different plans of treatment.

In infection by the pathogenic group of bacteria, local treatment is of little avail, unless instituted early, and it should be vigorously and systematically carried out, even at the risk of being superfluous.

The curette should not be used except in the early stages.

When infection is localized to the uterus and adnexa, recovery is the rule, and tonic and supporting treatment the indications.

If suppuration ensues, the abscess should be drained as soon as the diagnosis can be made with certainty.

Most cases of peritonitis which recover by the expectant plan of treatment are localized.

In sthenic cases of peritonitis, surgical interference is not only justifiable but the rational mode of treatment.—*Am. Lan.*

It takes 4,000 pounds of fresh rose petals to produce 1 pound of attar of rose, or 250 pounds for 1 ounce.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, FEBRUARY 11TH, 1893.

EDITORIAL.

INNOCENTS ABROAD.

For a long time it was considered 'quite the thing' for the young American physician to feel that life had been a miserable failure until a European trip and a course of study at Vienna had crowned a period of severe, industrious and painstaking work at home.

The diploma from the University of Pennsylvania, from Jefferson or Harvard, was but an ink-splotched and ribbon-bedizzened rag, whose Latin hieroglyphics merely served to remind him of the ponies which, in college days, he rode through classic fields; or, more likely still, to emphasize the fact that he had had no college days, but that his education, like Topsy, "had jis growed." His soul thirsted for the rathskellers of Deutschland and his sandaled feet, metaphorically speaking, unconsciously aligned themselves at right angles to the Atlantic Ocean. It was forgotten that of the greatest physicians and surgeons of this country, few ever saw a foreign city or heard a foreign teacher till fame had heralded them for many years; and, that when they did go abroad they went as honored guests and not as callow students.

In former days a course of study in a trans-atlantic medical center may have added much to both reputation and resource; for clinical instruction was long systematized in European capitals ere, in America, the didactic lecture ceased to be the sole reliance of both teacher and taught.

While clinical teaching is not the basis of *all medical knowledge*, it is the warp and woof of all that is valuable in finishing the practical part of a medical and surgical education. A physician without clinical training, is like a book-made soldier who, while coming to a conclusion according to the latest and most approved authorities, is promptly vanquished by the enemy.

The superior advantages of a European course in practical medicine are no longer visible to the naked-eye, but the mania for foreign titles and foreign degrees has not yet died out. Hordes of American students every year migrate across the At-

lantic seeking diligently to "gild refined gold or paint the lilly," by sitting at the feet of some stupid privat-docent. Fondly imagining that the ancient history they pay so much to hear is a message from on high, which they are the favored ones to carry back to their benighted countrymen. Countrymen, who have either had too much sense, or have been too poor to reap the rich and abundant harvest of wisdom vouchsafed only to those who have been fortunate enough to puff at a meerschaum 'unter den Linden.'

There is some excuse for one, who, attracted by the marvelous results and the wonderful, almost poetic skill of a man like Lawson Tait, wishes to catch a glimpse of the man and of his work. For Lawson Tait is a genius, an iconoclast and a teacher for the ages, a great land mark of his time. It is the running after a set of men whose published statistics show them to be operators inferior even to the average in this country, that fixes the crown of Bottom on the tender brow of innocence.

It is time the world knew, and that all Americans should recognize the fact that surgeons are working right here in Philadelphia, whose skill is unequaled, whose results have never been surpassed, and whose works cannot be duplicated by any man or set of men in Europe. The professional latch-string of these men hangs outside and may be pulled by any deserving man at a moment's notice.

If it is special schools that the young or the old graduate sighs for, surely the polyclinics and the special hospitals of New York and Philadelphia can furnish instruction so varied and material so abundant that the most industrious and ambitious can neither observe nor in any manner utilize it all.

Let American students conquer what we have, before they sigh, Alexander like, for other worlds.

There is no room for snobbery in medicine. A truth developed, a method evolved, a remedy discovered, a disease conquered, or a doctrine put forth in America should produce as profound an impression upon us as if its author enjoyed the delights of existence upon the banks of the Rhine, the Seine, or the Thames.

Truth is universal and knowledge makes the whole world akin. Provincialism is narrow and science is independent of patriotism, yet a decent regard for one's own country and the achievements of one's own countrymen is at all times a laudable spirit. To worship at foreign shrines just *because* they are *foreign* is a more detestable spirit than that mole-eyed selfishness which sees nothing good, hears nothing worthy, and says nothing commendable of any thing or person outside of its own narrow horizon.

The study of medicine should be pursued for the love of truth and for the good of humanity. The desire to shine by borrowed light is a spirit as foreign to the true student's mind, as is a spirit that can see an element of the ludicrous in the maimed and distorted bodies thronging the waiting rooms of physicians, seeking relief from hideous disease and pain.

He who pursues science because he would store his mind with great truths, who has sought admission to the ranks of a great profession because he feels more at home ministering to the unfortunate and the stricken, need go no further than to the metropolis of our own country to see, to hear and to acquire all that can be learned anywhere.

Savings for Servants.

In Germany every servant girl is obliged to own a little blank book for stamps. Once a week the mistress pastes in the book a two-penny-half-penny stamp, which is purchased from the government. When the girl gets old, or should she fall ill, the stamps are redeemed by the government, so that the girl has a small sickness or old age fund. This custom was ordered by the Emperor about two years ago.—*Ex.*

TRANSLATIONS.

Theory of the Phagocytes.

Metchnikoff (*Le Bulletin Medical*, Jan. 22d,) contributes an article on the theory of the phagocytes. He says these cells, that are capable of surrounding foreign bodies by means of active movements, are denominated phagocytes. Sometimes the entire individual is a phagocyte, capable of enclosing the foreign bodies; such are among the protozoans, the amebæ, the rhizopods, and the majority of the infusoria. In certain inferior animals—the sponges for example—the majority of the cells only are phagocytic. The question now arises, in the vertebrates, the mammiferæ, man, which are the cellular elements capable of manifesting these properties? These elements may be divided into two great groups according as to whether they are mobile or immobile. The *mobile* elements, the most numerous, are confounded with the leucocytes from which they must be distinguished.

The smallest leucocytes, the lymphocytes, which scarcely have the dimensions of the red corpuscles, have a large nucleus which the basic aniline colors stain with great intensity, and very little protoplasm which stains to a much less degree than the nucleus. These are found in large numbers in ganglia, in the corpuscles of the spleen and in the marrow of bone. They appear to be the young stage of leucocytes.

The mononuclear leucocytes, properly so-called, are distinguished from the preceding by large size and method of coloring; their protoplasm, abundant, is pretty well stained by the basic colors; their nuclei, rich in nuclear juice, take a color less pronounced than the nuclei of the lymphocytes; also the difference between the nucleus and the protoplasm is less marked. The nucleus, single, is often oval, may be lobulated and frequently reniform. These two categories only represent a small part of the leucocytes, about twenty per cent. in human blood. The great majority is formed by the polynuclear leucocytes (Ehrlich.) These are round or ameboid cells presenting a lobulated nucleus, but nearly always single: it is very rarely that they are truely polynuclear. In fact, the nucleus is composed of several lobes united by filaments often extremely minute. These lobes are at times so numerous that the nucleus presents in its entirety the appearance of a mulberry. A very frequent form is the trefoil; at times rays unite all the lobes. The aniline basic colors stain all of the nuclei with great intensity, which resemble, in this respect, those of the lymphocytes. They contain a great deal of chromatic substance and very little nuclear juice. The protoplasm stains very feebly, often not at all, with the basic colors, differing thus from that of the two preceding groups. These polynuclear leucocytes represent 70 to 75 per cent. of the leucocytes. There still remains five per cent. of white corpuscles, represented by those which resemble at times the mononuclear and at times the polynuclear leucocytes, but differ from them in the special staining of the granules which fill the protoplasm. The most of these are represented by the eosinophile leucocytes, the remainder by the cells of Ehrlich.

Ehrlich's cells have their protoplasm filled with granulations which are only colored by the basic coloring matters. These granulations, round, of variable dimensions, have often been confounded with cocci. They may be distinguished by the colorless space in the centre of the mass, which represents the nucleus of the cells incapable of taking any stain. These leucocytes are extremely rare. They are especially found in pathological connective tissues. Some, for instance, in the spleen; they are very numerous in the lymph.

The eosinophile leucocytes have an oval or lobulated nucleus—thus analogous to those of the polynuclear—which is well stained by the aniline colors. With no basic color whatever are the granulations stained, even feebly. It is of no consequence what acid color, on the contrary, may be used, however diluted, but the granulations are very strongly stained and fill nearly the entire cell, leaving very little room for the protoplasm. The eosinophile leucocytes are always found in the blood of vertebrates. They sometimes have an elongated form, sometimes a crys-

†Translated for THE MEDICAL AND SURGICAL REPORTER by W. A. N. Dorland, M. D.

talline appearance, particularly in certain reptiles and birds. They represent four or five per cent. of the white corpuscles of the blood and are especially prevalent in the marrow of bone.

In certain animal species, the rabbit and the wolf for example, but never in man, cells are found with granulations stained by eosine, which have been confounded with eosinophile leucocytes. Their granulations are smaller and in much smaller number, rarely filling the entire cell. These granules also take the basic colors, which is never done by the true eosinophile leucocytes. These cells have been denominated pseudo-eosinophile or amphophile. To distinguish them care should be taken not to leave the preparation a long time in the basic bath. In man, who has not these amphophile cells, a variety is found, without doubt corresponding, with granulations which are only colored by an acid and basic mixture; they are the neutrophiles.

In several species of mammiferæ—in the dog among others—no species of cells with granulations is found; it may be that they exist, but that the method of coloring them has not yet been discovered.

Which of these classes present phagocytic properties? Neither the lymphocytes, nor the eosinophiles, nor the cells of Ehrlich ever contains, in spite of their ameboid movements, foreign bodies, a truth which proves, it may be said in passing, that the pretended viscosity of the ameboid cells is not the cause of the encircling. Only the mononuclear, the polynuclear, the amphophiles and the neutrophiles enclose foreign bodies. According to the case, it is the one or the other category which plays the principle role.

In studying tubercle we have seen along side of the white corpuscles equally capable with them of enclosing foreign bodies, some immovable cells—the endothelial cells of vessels and nervous membranes—which present great analogies to them. Their protoplasm is stained by the basic colors as well as their nuclei, in which the nuclear juice is very abundant. When these cells are detached from the vessel walls and carried into the blood current, they are often difficult to distinguish from the leucocytes.

The analogies between these different groups of cells with large nuclei, single, are so great that they have been united under the general name of macrophages, reserving that of microphages for white polynuclear globules capable of surrounding foreign bodies. All of these phagocytic cells present the common characteristic of being derived from the mesoderm. In the muscular and nervous tissues there are other fixed phagocytic elements more specialized. In the muscular fascicles it is not the myoplasm, but only the interstitial substance or sarcoplasm, which fills the phagocytic function; as may be noticed in certain pathological cases, where the sarcoplasm, forming a large number of buds, surrounds, destroys, digests the myoplasm. The cells of nervous ganglia also manifest phagocytic properties and, it is probable that the cells of the neuroglia also have analogous properties.

What relations have these phagocytes with the micro-organisms? The phagocytes are endowed with a certain sensibility denominated chimiotaxia. They discriminate between foreign bodies and do not encircle them indifferently. Especially is this manifested towards various bodies in solution, and above all towards substances of bacteric origin. If, after the introduction of microbes in o the organism, there is produced at first a considerable leucocytosis, and if the leucocytes direct themselves in large numbers towards the point of introduction, it is said that there is a positive chimiotaxia. If, on the contrary, the number of the white corpuscles diminishes, and if, at the point of introduction there is formed a simple serous exudate without leucocytes, it is said that there is a negative chimiotaxia. The more receptive an organism is the more is the negative chimiotaxia manifested; the more refractory an organism is, the more is the positive chimiotaxia noted. If by vaccination a very sensitive aninal is transformed into a refractory, the chimiotaxia, at first negative, becomes positive.

The encircling of microbes by the leucocytes is an active protoplasmic act and not simply mechanical due to a pretended viscosity of the protoplasm. It is a physiological act on the part of the leucocytes and not on the part of the microbes. Metchnikoff has seen a very mobile spirilla in relapsing fever unable to introduce itself into the globules. The process then

may be compared to an intra-cellular digestion, and in the process a difference in the method of fixation of the colors may be seen. The microbe, at first quite colorless, colors all at once with a great intensity, a proof of its death; then, little by little, the color disappears until it finally disappears entirely. Therefore the phagocytes surround and digest the microbes. If some leucocytes enclosing microbes are transported to a drop of nutritive substance, in a little while the leucocytes die, while the microbes, finding a favorable medium for their development, multiply in the interior of the phagocytic cell. Very soon this is filled, the peripheral protoplasmic bed is traversed and the microbes diffuse throughout the liquid. This is proof incontestible that the microbes have been encircled while living. The tubercle bacillus is distinguished by its great resisting power to this action. It is surrounded; sometimes it may be digested, but more often it resists, ends even by destroying the cell, and then is able to invade the organism.

The spores of the bacteria often resist the destructive action. Sometimes they may be digested, as, for example, those of the bacillus of tetanus. But more often they are not affected, the bacilli themselves being destroyed. This shows that in certain cases the phagocytes are protectors and not in others. This clearly demonstrates that it is the cellular elements, the phagocytes, which retard invasion and not the liquids of the organism. The principle method of defense of the organism then is the phagocytic action. Perhaps there may be other methods; it is very probable. At any rate it seems to be very clearly demonstrated that this protective power should not be ascribed to the humors of the body, which in general, and even in protected individuals, are an excellent medium of culture.

Radical Operation for Umbilical Hernia.*

R. Condamin., (*Arch. prov. de Chir. T. I.*, p. 193). The tendency of umbilical hernia to become larger or to produce pain of often a functional or sympathetic character, together with the difficulty or impossibility of keeping in place by bandages, makes it necessary to study carefully the technique of radical operation. C. has found it more satisfactory to make a total extirpation of the umbilicus, to freshen the inner marginal sheathes of both recti, and uniting the abdominal wound by three rows of sutures. The first unites the peritoneum, the second (which is of the greater importance) unites the two opposite leaflets of the recti. The third unites the skin.

In order to insure close apposition of the various parts, he recommends placing a silver suture deep in both angles of the wound.

Peptonuria in General Paralytics.†

The greatest discord as to the pathology of peptonuria exists among alienists as well as among practitioners. In general paralysis, Maccabruni has only seen it four times in forty-five patients. Marro found it in every instance in twenty-two patients. Fronda has had under observation seventeen paralytics and has made twenty-eight analyses of the total urine of the twenty-four hours; three times the peptonuria was not found at one or two analyses, but was noticed subsequently. A fact worthy of note is that it was not present once during a period of excitation but appeared during a period of calm. This is contrary to the usual hypothesis, according to which it should be produced and eliminated more during cerebal activity.—R. Fronda,(*Il Manicomia Moderno*, Anno VII, No. 1, 1892, pp. 1 to 18.

Not Deserving of Recognition.

"By the way," said the gentlemanly looking person in the black broadcloth suit, "if you mention my name in connection with the accident you may say that 'Dr. Swankem was called and the fractured arm was suitably bandaged,' or something to that effect. Please spell the name correctly. Here's my card."

"Thanks," said the reporter, looking at the card. "You are next door to Dr. Rybold, I believe. Are you acquainted with him?"

"No, sir," replied Dr. Swankem, stiffly. "We do not recognize Dr. Rybold as a member of the profession. He advertises."

†Translated for MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

BACTERIOLOGICAL NOTES.

The Growth of Bacteria through the Pasteur-Chamberland Filter.

The fact has been asserted for a considerable time that the Pasteur-Chamberland filter was not proof against bacteria. This was disappointing as it was hoped by all, and believed by many, that the Pasteur filter would remove all organic, as well as inorganic, material from the water which passed through it. Several tests have been devised for proving the passage of bacteria through the *bougie* of the filter. Smith and Moore (*Centralblatt f. Bakteriologie Parasitenkund* xii., 1892, p. 628) describe an extremely simple method. A bougie from an ordinary Pasteur filter is inverted in a large glass tube the top of which is plugged, about the bougie, with cotton. It is then sterilized by dry heat. A culture of the germ to be tested, which has grown for a few hours only, is transferred to the tube by means of a sterilized pipette. By means of air pressure a portion of the liquid is forced through the bougie into the tube. The filtered liquid is perfectly clear. The entire apparatus is then placed in an incubator. The filtered culture liquid in the tube will remain clear until it is rendered turbid by the multiplication of bacteria which have grown through the walls of the *bougie*. The authors found that the hog cholera germ would grow through the tube in from five to ten days. The experiments made were sufficient to show that the pores in the tubes are large enough to admit of the passage of bacteria the size of the cholera spirillum or the typhoid bacillus. They also show that there is a difference in the pores of different tubes. [These facts confirm in a measure the statement of M. Dujardin-Beaumetz that, "filters are of no use whatever, and thus another cherished illusion is likely to disappear." The fact should be borne in mind that, thus far, there has been no filter devised that is capable of turning out water "germ free" after it has been in use for a considerable time. The only safe and reliable method of obtaining wholesome drinking water is, if the water is cloudy from holding earth in suspension, to filter it to remove the dirt, boil it to destroy the bacteria and keep it until used in a sterilized vessel placed in a refrigerator. This is important at all times, but more especially during the coming season when cholera may dangerously contaminate the water supplies in many sections of our county.—Ed.]

The Micrococcus Lanceolatus, with special reference to the Etiology of Acute Lobar Pneumonia.

Prof. Welch (*Bulletin of the Johns Hopkins Hospital*, iii, 1892, p. 125) has begun a series of articles on the etiology of lobar pneumonia which will be welcomed by all physicians. The first part consists of a review of the discovery of the germ by different investigators, and an exhaustive discussion of its morphology, biology and effect upon experimental animals. A complete list of the synonyms is also given. *Micrococcus lanceolatus* is preferred from the fact that the names, pneumo-coccus, micrococcus pneumoniæ cruposæ, and diplococcus pneumoniæ suggest an exclusive relationship of the organism to acute croupous pneumonia, whereas this same organism is concerned in the causation of cerebro-spinal meningitis and many other affections independent of pneumonia. The germ was first discovered by Sternberg in 1880, by inoculating rabbits with his own saliva. It was next found by Pasteur three months later. Within the next few years the germ was discovered and named by a large number of investigator. It was found not only in the sputum but in lungs affected with croupous pneumonia. The two discoverers whose names are most frequently associated with the germ of pneumonia are Friedländer and Fraenkel. Friedländer's pneumo-coccus, however, has not been demonstrated as bearing any relation to pneumonia whatever. Morphologically the micrococcus lanceolatus is an oval organism with one end somewhat smaller and more tapering than the other. In cultures oval and frequently spherical forms can be found. The average length of the germ is about 1–1.5 *m* its thickness from ⅓ to ½ that of its length. Its typical form is transitional between a coccus and a bacillus. By Flügge it is called a bacillus, and Beck, of Koch's Institute, calls it the diplo-bacillus of Fraenkel. The author retains the name micrococcus

instead of bacillus on account of the customary usage. The cocci are arranged in pairs usually, frequently in short chains.

Welch found that from cultures of typical diplococci he could sometimes obtain, in later generations, non-virulent streptococci which could not be distinguished from some cultures of the streptococcus pyogenes. If this germ of pneumonia occurs under natural conditions in similar chains there seems to be no way of separating it from some other varieties of streptococci. As an aid to diagnosis there are three characters which, if carefully observed, may render the identity of the germ reasonably certain when it is examined in cover-glass preparations made from the tissue, these are: (1) the lanceolate shape; (2) the paired arrangement; and (3) the presence of a capsule surrounding the organism. The capsule can be demonstrated around the germs growing in the tissues and liquids of the animal body. The capsule is frequently demonstrated when the germs have been developed on blood serum and agar and in milk and bouillon. Welch found that degeneration and involution forms of the micrococcus lanceolatus were common in cultures and in the animal body especially in old inflammatory exudates. The most interesting of these forms were empty capsules and capsules containing feebly or unstained cocci, or deeply stained particles in stained preparations.

The micrococcus lanceolatus grows best at a temperature about that of the human body. It can be cultivated on all of the ordinary culture media. Gelatine is not well adapted for obtaining the first cultures, as the growth is not sure at a temperature below its melting point. Slight variations in the composition of the media or its chemical reaction will often deter and frequently check the development of cultures. The media should be feebly alkaline. It does not liquify gelatine; milk is usually soured and coagulated; a small quantity of acid is produced in bouillon; no growth or a faint grayish growth on potatoes; it is faculative anærobic growing without as well as with the presence of oxygen. The maximum development in cultures, at the body temperature, is attained in twenty-four hours or less.

The virulence of the pneumonia germ is variable. Cultures were obtained that were devoid of any virulence. They were also obtained so virulent that a very small quantity was capable of killing rabbits by septicæmia in less than twenty-four hours. Mice were more certain to die than rabbits. Guinea pigs and dogs were much less susceptible than mice and rabbits. Rats and cats were still more resistent, but could be destroyed by larger doses of the virulent cultures. Chickens and pigeons are insusceptible. The pathological effects of large and smaller quantities of the virus when inoculated into all of the susceptible experimental animals are carefully described.

The Differentiation of the Typhoid and the Coli Communis Bacilli.

Wurtz (*Le Bulletin Med.*, 1891, No. 100, p. 1155) gives a very simple method of distinguishing between these bacilli. If they are cultivated on a solid medium containing lactose and sufficient litmus to give it a blue color, the results are as follows: In the culture of the typhoid bacillus the color remains unchanged, while in the culture of the coli communis bacillus the lactose is converted into lactic acid which changes the color produced by the litmus from the blue to a red.

From the investigations of Chautemesse and Widal it is known that, upon solid media upon which the typhoid bacillus has grown for at least eight—ten days and the growth removed from the surface, that a subsequent inoculation with the typhoid germ will not develop, while an inoculation with the coli bacillus will produce a vigorous growth. [After studying the morphology of the suspected germ, and its growth in gelatine rolls, which is quite characteristic of the coli bacillus, a very conclusive test is to cultivate it in bouillon containing two per cent. glucose, in a fermentation tube. The typhoid germ will produce no gas while the bacillus coli communis will produce a considerable quantity of gas which will collect in the closed end of the tube.—Ed.]

Pulmonary Hemorrhage.—If severe, raise the thorax, administer opiate; gallic acid, fifteen grains, every fifteen minutes; ergotin, five to ten grains hypodermically, two or three times daily; ice bags to the chest; as a last resort a ligature may be thrown around the larger limbs. (*Tyson*).

ABSTRACTS.

PATHOLOGY OF CARCINOMA.*

Dr. H. C. Coe read a paper on this subject before the New York State Medical Society. The reader introduced his paper by a reference to the great interest which had been aroused in cancer within the past five years and the hope that its mystery would be solved by the aid of bacteriology.

Various theories have been advanced regarding its nature, many of which were fanciful, others quite suggestive. These were viewed in turn down to the latest investigations on the parasitic origin of the disease. They all contained the central idea that the disease was in the nucleus of the cell itself, the cell being really infectious. Under certain degenerative conditions the normal epithelial cell might be susceptible to external infection, perhaps by the entrance of coccydia and thus assume a new malignant character. Metastasis was simply infection in distant localities by cells carried through the lymphatics from the parent growth. It should be carefully distinguished from direct extension of cancer to the tissues surrounding the neoplasm; this distinction was important from a surgical standpoint. Cancer was formerly regarded as a "cachexia," but this term was now rejected, the condition being simply a depreciated condition of the general system such as was present in all wasting diseases. Cancer like tuberculosis might be local or general.

Heredity was a factor of minor importance. Even persistent local irritation must be supplemented by some degenerative process in the epithelial cells at the point of irritation. The same applied to the cancerous transformation of benign neoplasms. The inflammatory changes *within* a cancerous tumor were essentially destructive, while those *around* it might be conservative, limiting the extension of the disease. It had been shown that outlying groups of cancer cells might be destroyed by an acute inflammatory process. The following practical deductions were made: The possibility of general or constitutional prophylaxis was purely theoretical. "Local" prophylaxis consisted in the prompt removal of a suspicious growth or tissue in the pre-cancerous stage, i. e., while it was still merely suspicious—as in the case of the eroded cervix uteri. It was possible that a specific might yet be found, such as had been sought for tuberculosis, etc.

Surgically the only rule to follow was *early* and *complete removal* of the cancerous neoplasm, even at the risk of subsequent deformity. Since it had been demonstrated that inflammatory processes might actually destroy groups of cancer cells within adjacent healthy tissue, union by first intention might not be so desirable as has been thought. The ultimate condition of the patient was the first consideration, not the rapid and non-suppurative healing of the wound. Patients must be educated to the necessity of radical removal of the growth at its incipient stage if a radical cure is to be expected. Reference was made to Robinson's and Byrnes's results with caustics and the galvano-cautery. With regard to the palliative treatment of cancer by operations enough praise could not be bestowed upon the results of modern surgery. With greater knowledge, increased skill and improved technique, these would continue to improve. We were not justified in holding altogether pessimistic views with regard to the surgical treatment of cancer.

The reader concluded with a tribute to the pathologists whose work was too often undervalued by practical surgeons, but to whom Medicine was indebted for the wonderful advance which it has made in the past decade.

*Special Correspondent to THE MEDICAL AND SURGICAL REPORTER.

"Why are you so naughty, Johnnie? It seems to me that with mamma worn out, and papa with a broken arm, you might try to be good."

"Hoh!" said Johnnie. "That's just the time to be bad. No one can lick me for it."

"Going up to Bradley's for Sunday?"

"Yes."

"Well, look out for squalls."

"Why? Bradley's not quarrelsome."

"No; but he has a new baby."

CURRENT LITERATURE REVIEWED.

THE VIRGINIA MEDICAL MONTHLY

for February contains a paper by Dr. W. P. C. Hazen on

A Question Relative to the Treatment of Diphtheria.

After reviewing the opinions of various observers, the author concludes that the disease heretofore called diphtheria should be looked upon "as two distinct diseases, namely diphtheria, resulting from the action of the Klebs-Loeffler bacillus, and pseudo-diphtheria, resulting from the presence of other organisms." On agitating a doubtful membrane gently in water, if it does not fall apart, but remains in resisting and elastic layers, there is no doubt that it is diphtheritic. The absence of the knee-jerk is said also to be proof positive of diphtheria. In the treatment, he advises spraying the throat with peroxide of hydrogen, followed in an hour by the application of a five per cent. solution of the oleate of mercury—the hydrogen peroxide being alternated every hour with the mercury. The oleate of mercury serves the same purposes as the bichloride, without its irritant qualities. In the internal administration of remedies, the practitioner must be guided by circumstances and his own good sense. With the exception of stimulants, there are no medicines the author would particularly recommend. Iron he regards as useless.

Dr. William R. Howard contributes a paper on

Puerpural Infection

the direct cause of which are microbes and their products, ptomaines and leucomaines. The author rightly regards prophylaxis as most important. Strict antisepsis in the delivery, the avoidance of lubricants—soap, oils and fat, and as few examinations as possible are his rules. In the treatment he considers antiseptic intra-uterine douches of value in the early stages. The uterus should be scraped with a blunt curette if there is reason to believe that there are shreds or decomposing clots in the cavity, but after the inflammation has extended to the tubes, ovaries, peritoneum, etc., he rightly considers curetting useless and condemns the procedure. Quinine in four to six grain doses should be given every four to six hours. He does not believe in the use of Epsom or Rochelle salts, stating that little is needed to move the bowels other than an occasional enema, which may contain turpentine if much flatus be present. [In our experience, we have found that free purgation by means of a saline, has removed seemingly threatening symptoms.—ED.]

Dr. James Kerr, in an able paper, discusses "Laparotomy in Shot Wounds of the Abdomen." The "ostrich plan" of giving opium and making the patient comfortable is mentioned only to be condemned. The literature of the subject is carefully reviewed, as is also the technique of the operation. The paper includes the report of two cases operated on by the author and a table of operations to date.

Dr. F. Pearson contributes a paper on

The Food of Cholera Germs.

According to the author, cholera epidemics in the United States have occurred in places where limestone water abounds. His conclusion is that there is a deposit formed by the water in the intestinal canal which is peculiarly favorable to the nutrition of the comma bacillus. He mentions the observation of Dr. R. G. Curtin, at the Philadelphia Hospital, that those persons drinking a lemonade of weak sulphuric acid were not attacked by the disease. According to the author, the reason for this immunity lies in the fact that the intestinal deposit of lime will be broken up and dispelled by the acid. The paper also points out the fact that it is not always the filthiest community which suffers most severely from the cholera.

Dr. J. C. Hurst considers the subject of the

Etiology of Decay in Teeth,

pointing out the fact that inorganic material is necessary for the proper maintenance of the enamel. In our civilization, we have almost completely banished inorganic substances from our chief article of food—bread. The refinements of milling flour have totally removed all the bran, in which all the inorganic material principally exists. The remedy, according to the author, lies in a return to the coarser bread of our forefathers. "In our bread, let the entire grain enter—bran and all—at each meal. Then, not until then, will we die that death which is a physiological process, with a mouth full of healthy teeth."

Dr. H. Augustus Wilson describes

A Simple Tourniquet Clasp

for the elastic tourniquet or the Esmarch's bandage. In shape it is like the letter S and is used by being fastened by its middle bar to one end of the tourniquet, the free end of the tourniquet being slipped under the upper and lower loops of the letter as in an ordinary buckle. By its means, compression may be made without using the whole length of the strap, as is necessary in the ordinary variety, furnished with a chain and hook for fastening. The instrument is made out of ⅛ inch German silver wire.

Dr. H. Berlin in an article on "The Albumen Reaction—Resemblance of Piperazine in Urine," points out the fact that such urine gives the albumen reaction with the picric acid test. It is said not to do so with the nitric acid test.

Other articles in this number are: "Foreign Bodies in the Eye," by Dr. S. Latimer Phillips; "Some Points in the Diagnosis of Cutaneous Diseases," by Dr. James C. McGuire; and "Concerning the Use of Cocaine in Enucleation of the Eye," by Dr. John Dunn.

Under Clinical Reports, Dr. H. P. Wenzel reports an "Aneurism of the Aortic Arch" which ruptured into the œsophagus, causing death almost instantly. Dr. Mark W. Pryor Peyser reports a "Case of Shoulder Presentation," necessitating embryotomy, and which was followed by the death of the mother on the tenth day from peritonitis, "due probably to the escape of the lochia through the fallopian tubes."

THE ST. LOUIS MEDICAL AND SURGICAL JOURNAL

for January, contains a paper on "The Medical Corps of the Army and Navy of the Confederate States." The formation, number and services of the medical staff of the Confederacy during the war are narrated, and a high tribute paid to the men who labored hard for the relief of suffering on the Southern side.

Dr. John W. Trader utters a solemn word of warning against

Gynecological Excesses

in a paper read before the Pettis County Medical Society in November last. The author thinks that the mind of womankind is too generally directed to the organs of generation as the *fons et origo* of their ailments, and therefore a pelvic examination is too often demanded of the gynecologist by the patient and undue treatment is inflicted on the long suffering uterus. He thinks women are apt to boast of this or that operation having been performed on them. "Jenny had her womb straightened by Dr. Blank" is too often the boast of the mother. Luxury, and the licentiousness bred of luxurious living, come in for their share of blame. Education of men and women in regard to the sacredness of their bodies and the teaching of purity in thought and deed would do much to diminish the work of the specialist in the diseases of women.

"Optometry" is the title of a lecture by Dr. Flavel B. Tiffany, delivered to the class at the University Medical College of Kansas City. The various eye tests and the instruments used are described. The paper is illustrated by cuts of instruments and photographs of the methods of use.

This number concludes with a lecture by Dr. Thomas J. Mays on "Asthma." Strychnia, hyperdermically or by the mouth, is advocated in the treatment and a number of cases are reported.

THE COSMOPOLITAN FOR FEBRUARY.

This magazine is rapidly gaining an international reputation as one of the foremost of American publications. The more interesting of the articles include an illustrated essay on naval construction, showing its evolution from the galley of the Spanish armada to the battle ship of to-day; a fanciful sketch "June, 1993," which is a not very good romance of the "Looking Backward" style; an instructive article on the A. T. and S. F. R. R., and several short stories. Other leading articles are "Monte Carlo," a hamdsomely illustrated sketch of this great gambling resort;" "Sugar from Sunbeams," telling how beet sugar is made, and a eulogistic article on Blaine. It is certainly a quarter's worth—this February Cosmopolitan.

PERISCOPE.

THERAPEUTICS.

Substances Incompatible with Antipyrine.

The following substances precipitate antipyrine from its aqueous solutions:

(1) Concentrated solutions of carbolic acid.

(2) Tannin, and preparations containing tannin.

(3) Tincture of iodine.

(4) The chlorides of mercury.

The following substances, when triturated with dry antipyrine, decompose it:

(1) Calomel, which forms a toxic compound with antipyrine.

(2) Beta-naphtol.

(3) Choral hydrate, which forms an oleaginous liquid with it.

(4) Sodii bicarbonas, which when brought in contact with it sets free an odor of acetic ether.

(5) Salicylate of soda, which also forms an oleaginous compound with it.

(6) The salts of quinine and caffeine, which have their solubility increased by antipyrine.—*Gaz. des Hopitaux.*

Subcutaneous Injections of Normal Nerve Substance in Epilepsy and Neurasthenia.

Babes (*Deutsch. Med. Woch.*, July 28th, 1892) records the results of this method of treatment in a large number of patients. Normal brain and spinal cord were made into an emulsion with broth in the proportion of 1 gramme of the nerve tissue to 5 grammes of broth. Of this 4 to 5 grammes were injected in the abdomen or flank five to six times a week in epileptics, and four to five times a week in neurasthenics. A large number of epileptics were cured, and others greatly improved. Good results were also obtained in melancholia, neurasthenia, and cases of slow heart action. A case of sleeplessness, in which all known narcotics, even in large doses, had failed, was cured after three injections. A patient with cephalalgia of over a year's duration was remarkably improved after seven injections. Syncopal attacks and a paralytic condition in another patient disappeared after sixteen injections. Sciatica of a month's standing was cured by three injections.

After-Effects of Chloroform.

Luther (*Munch. Med. Woch.*, January 3rd, 1893,) says that changes are found in the kidneys after death by chloroform, however, produced. He says that after almost every administration, especially if prolonged, albumen and casts appear in the urine. The author has found that (1) the urine was normal when no after-effects, such as vomiting, etc., were present; (2) of many cases examined the after-effects were most marked in the single case in which abnormal constituents were found in the urine; (3) albuminuria and cylinduria go hand in hand, and disappear after a few days, and (4) the casts are mostly hyaline. He concludes for these reasons that (1) the use of chloroform should be limited to cases where it is necessary; (2) in every case before prolonged narcosis the urine should be examined, renal disease being a more important contra-indication than heart disease (except fatty heart); (3) chloroform narcosis should be restricted in the case of the pregnant and lying in, and it should be absolutely avoided in eclampsia, since it must be prolonged, and the kidneys are nearly always diseased; and (4) mild diuretics are of value in the after-effects of chloroform.

The Effects of Acids on the Functions of the Stomach.

1. Acids throw down a considerable precipitate of mucous.
2. They increase the cellular elements of the gastric contents.
3. Their introduction is followed by butyric-acid reaction, most marked after hydrochloric acid.
4. Larger quantities of the acids result in a considerable effusion of bile into the stomach.
5. They stimulate the secretion of pepsin, but have no influence upon the secretion of hydrochloric acid.
6. Their long-continued adminstration is followed by marked diminution of the secretion of hydrochloric acid.
7. Even in large quantities hydrochloric acid produces no gastric disturbances. On the contrary, a continued administration of the acid is attended with a feeling of well being.
8. The difference in the effect between acids and the alkaline salts on the gastric functions consists in the fact that the alkaline salts dissolve the mucous and decrease the secretion of pepsin, while the acids precipitate the mucous and increase the secretion of pepsin.

The disappearance of the alkaline salts from the stomach is followed by a decided increase of the hydrochloric acid secretion. This does not occur, or only to a slight degree, in the case of acids. Both the acids and salts, in large quantities in continued use, have the same effect in lowering the activity, and finally in destroying the function of the glands secreting hydrochloric acid.—*Jaworski, in Centrlablatt fur Klin. Med.*

MEDICINE

Antisyphilitic Treatment—Proper Duration.

This is one of the most interesting and, as is well-known, most disputed questions of medical practice. The physician is often puzzled in making a proper choice, and in the end, and after much hesitation, generally decides upon what, in his experience, has been the mean duration of treatment. But how often do we see patients who, after having been under medical supervision for a length of time, abandon the doctor to treat themselves—believing themselves to have a sufficient experience to permit them to do so, and thus destroy their constitution by a too prolonged use of mercurials when the latter are no longer indispensable, yea, often even harmful!

In a communication to the Paris Societe de Therapeutique, Dr. Bonetemps, of Saumuz, supported the doctrine of Prof. Fournier, who asserts that in no case can the duration of the antisyphilitic treatment be fixed at less than three or four years. As, at the same time, the patients ought to observe in the medication certain alterations and periods of repose or dishabituation, Dr. B. has arranged the following table, a convenient vade-mecum for the practitioner:—

First Year
- 6 months of mercurial treatment,
- 3 months of potasium iodide,
- 3 months of repose.

Second Year
- 2 months of mercury,
- 5 months of iodide,
- 5 months of repose.

Third Year
- 2 months of mercury,
- 5 months of iodide,
- 5 months of repose and sulphur baths.

Fourth Year
- No mercury.
- Potasium iodine with intervals of
- Repose and sulphur baths.

Merck's Bulletin.

The Use of Strychnine and Digitalis in Diarrhœa.

In fevers of a remittent character Mr. Hendly says, the complication of persistent diarrhœa occurred frequently, and at periods when the patient was worn out by fever, and the digestive powers were rapidly failing, I determined to use these drugs to combat certain symptoms. In these cases the temperature ranges from 1° to 2½° above normal, the pulse is soft and yielding, not very rapid, and markedly wanting in tone; the motions four or five daily, increase in number until nourishment appears to excite an action of the bowels, marked by even a greater tendency to fluidity, the extreme being reached when the motions escaped involuntarily, and is followed by a tendency to cardiac failure, if not collapse, frequently accompanied by a consciousness of approaching dissolution in the patient. Digitalis was chosen for these cases because of its well-known general action upon the vaso-motor system; strychnine for its less known more direct action

upon that portion of the system concerned in the control of the blood supply to the intestines. The mixture employed was tr. digitalis, *m*iv; liq. strychniæ, *m*ij; spts. chloroformi, *m*v; in water, and repeated at from one to four hourly intervals.—*The London Practitioner.*

SURGERY.

A New Method of Gastro-enterostomy.

Postnikow, of Moscow (*Centralbl fur Chir.*, No. 49, 1892) describes a method of performing gastro-enterostomy in which the establishing of a free communication between the stomach and duodenum is postponed until the third or fourth day after the date of operation. The following are the stages of this method, which has been tried with complete success on seventeen animals:—(1) Incision of the abdominal wall; (2) attachment of the selected loop of small intestine to the anterior wall of the stomach by sutures passed beneath the serous coats; (3) excision of a small oval piece from the wall of the stomach as far as the muscular layer, and of a similar piece of the same depth from the wall of the small intestine; (4) union by means of sutures of the posterior edges of the raw surfaces thus established on the stomach and the loop of small intestine; (5) constriction by the silk thread of the portions of mucous membrane protrude at the wounded surfaces of the stomach and small intestine after removal of the serous coat; (6) union by sutures of the anterior edges of the opposed raw surfaces; (7) application of a second row of sutures passed beneath the serous coats; (8) closure of the external wound. In this operation the mucous membrane of the stomach and small intestine is not incised, but is closely constricted by two ligatures which, by causing gangrene of the protruded portions of these coats, and consequent separation, establish a free communication between the adherent parts of the gastro-intestinal tract. Postnikow states that by this method the escape of fæcal matter into the peritoneal cavity is prevented, the duration of the operation is shortened, and the necessity for washing out the stomach avoided.—*Br. Med. Jour.*

Transplantation of Bone.

Kapper (*Wein Med. Woch.*, No. 45, 1892) relates the following case. A strong, healthy woodcutter, aged 19, had been injured by the falling of a tree; a piece of wood pierced the right parietal region, he became insensible for a short time, and was taken to a hospital. There he suffered from pains in the head, and the injured part became much swollen. Eight days afterwards he left the hospital of his own will. Immediately after leaving the patient was seized with pain in the head, in the right eye, and in the wound. Ten days after the accident he came under Kapper's care. He then presented a wound the size of a shilling in the anterior part of the right parietal region, which was swollen, red and covered with granulations, and from which yellow pus was being discharged. The patient was narcotised and the wound enlarged; then the underlying bone was found to have an aperture in it from which exuded a quantity of yellow pus. This aperture was widened with a chisel, and between the cranial vault and the dura mater a piece of hard wood 3 cm. long, 2 cm. wide at its base, and ½ cm. thick was found implanted. This was removed, and the parts thoroughly cleansed; the wound was then drained and dressed with iodoform gauze. At the end of eleven days the wound was quite healthy. At this time the wound was opened up, and the cranial bones of a young goose several days old taken, cut up into eight small flattened plates, and then placed in the bottom of the wound upon the dura mater so as to fill up the defect in the bony wall of the skull; dressings of iodoform gauze were then applied and left on for ten days. On removing the dressings the bone had become partially consolidated. A few weeks afterwards the wound had completely healed, and the hole in the parietal bone was quite filled up with the newly formed bone.—*Br. Med. Jour.*

NEWS AND MISCELLANY.

State Board of Medical Examiners of New Jersey.

Candidates applying for a license (after the July, 1893, meeting of the State Board of Medical Examiners) to practice medicine in New Jersey, will be examined in the following subjects arranged in sections as follows, viz: Sec. 1, Materia Medica and Therapeutics; Sec. 2, Obstetrics and Gynecology; Sec. 3, Practice of Medicine (including diseases of the Skin, Nose and Throat); Sec. 4, Surgery (including Surgical Anatomy and diseases of the Eye, Ear and Genito-urinary organs); Sec. 5, Anatomy; Sec. 6, Physiology; Sec. 7, Chemistry; Sec. 8, Histology, Pathology and Bacteriology; Sec. 9, Hygiene and Medical Jurisprudence.

The following percentages will be required, also, after that date, before a license will be issued, viz: Candidates examined in the first class, i. e. graduates of five years or more, shall obtain a total average of eighty (80) per cent.; candidates examined in the second class, i. e. graduates of less than five years, shall obtain a total average of seventy-five (75) per cent., providing that in no one section shall the percentage be less than thirty-three and one-third (33⅓) per cent., in which case, however, should the total average percentage in all the other sections, be above seventy-five (75) per cent., the candidates may be granted a second examination, immediately, upon that section. Candidates examined in the third class, i. e. non-graduates, who have taken three full courses of lectures in a reputable Medical School shall obtain a total average of eighty (80) per cent., and candidates taking their preliminary or final examination shall obtain a total average of eighty (80) per cent., at each of said examinations.

TREASURY DEPARTMENT.
Office Supervising Surgeon-General, Marine-Hospital Service,
WASHINGTON, D. C., Feb. 11, 1893.

A board of officers will be convened at Washington, March 20, 1893, for the purpose of examining applicants for admission to the grade of Assistant Surgeon in the U. S. Marine Hospital Service.

The following is the usual order of the examination: 1, Physical. 2, Written. 3, Oral. 4, Clinical.

In addition to the physical examination candidates are required to certify that they believe themselves free from any ailment which would disqualify for service in any climate.

The examinations are chiefly in writing, and begin with a short autobiography by the candidate. The remainder of the written exercise consists in examination on the various branches of medicine, surgery and hygiene.

The oral examination includes subjects of preliminary education, history, literature, and natural sciences.

The clinical examination is conducted at a hospital, and when practical candidates are required to perform surgical operations on cadaver.

Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order, as vacancies occur.

Upon appointment the young officers are as a rule first assigned to duty at one of the large marine hospitals, as at Boston, New York, New Orleans, Chicago, or San Francisco.

After four years service, Assistant Surgeons are entitled to examination for promotion to the grade of Passed Assistant Surgeon.

Promotion to the grade of Surgeon is made according to seniority, and after due examination as vacancies occur in that grade. Assistant Surgeons receive sixteen hundred dollars, and Passed Assistant Surgeons eighteen hundred dollars, and Surgeons twenty-five hundred dollars a year. When quarters are not provided, commutation at the rate of thirty, forty, or fifty dollars a month, according to grade, is allowed.

All grades above that of Assistant Surgeon receive longevity pay, ten per centum in addition to the regular salary for every five years' services up to forty per centum after twenty years' service.

The tenure of office is permanent. Officers traveling under orders are allowed actual expenses. For further information, or for invitation to appear before the board of examiners, address,

WALTER WYMAN,
Supervising Surgeon-General,
U. S. Marine Hospital Service,
Washington, D. C.

The Section on Laryngology and Rhinology of the Pan-American Medical Congress is now thoroughly organized with secretaries in all the countries of South America as well as in the United States and Canada.

The President, Dr. E. Fletcher Ingals, of Chicago, is making a thorough canvass to secure a large number of good papers for the Section, and aided as he will be by the able Secretaries, Drs. Murray and y Alonso, and the corps of honorary presidents he feels assured of the success of this department of the Congress. All physicians interested in this Section are requested to correspond with the secretaries for the United States.

DR. J. MARON y ALONSO,
(Spanish Speaking,)
Las Vegas, N. M.
DR. T. MORRIS MURRAY,
(English Speaking,)
Washington, D. C.

ARMY AND NAVY.

FROM FEBRUARY 5, 1893, TO FEBRUARY 11, 1893.

A Board of Medical Officers, to consist of Colonel Charles H. Alden, Assistant Surgeon General, U. S. Army; Lieut. Col. George M. Sternberg, Deputy Surgeon General, U. S. Army; Major John Van R. Hoff, Surgeon, U. S. Army.

Captain Guy L. Edie, Assistant Surgeon, U. S. Army, is constituted to meet in New York city on the 27th day of March, 1893, or as soon thereafter as practicable, for the examination of candidates for admission to the Medical Corps of the Army, and for such other business as may be brought before it.

Leave of absence for one month, with permission to apply for an extension of one month, is granted 1st Lieutant Charles Willcox, Assistant Surgeon.

Captain Paul Shillock, Assistant Surgeon U. S. Army, promoted as such to date from January 31, 1893, in accordance with the act of June 23, 1874.

By direction of the Secretary of War, the order assigning Capt. Charles B. Ewing, Assistant Surgeon, U. S. Army, to duty as Post Surgeon, Fort McHenry, Md., is suspended until June 1, 1893, when he will comply with the order.

The leave of absence granted Captain Junius L. Powell, Assistant Surgeon, U. S. Army, is hereby extended one month.

To the Inauguration Via B. & O. R. R.

The Baltimore and Ohio Railroad announces that on the occasion of the Inauguration of Cleveland and Stevenson on March 4th it will sell excursion tickets to Washington and return at low rates. Tickets reading via the B & O. will be on sale at its own offices and at the offices of the principal railroad companies throughout the country. Tickets will be sold March 2d, 3d and 4th, and will be good for return journey until March 7th inclusive. For information in detail concerning time of trains, rates of fare, etc., address C. P. Craig, Gen'l Eastern Passenger Agent, 415 Brordway, New York; A. J. Simmons, New England Passenger Agent, 211 Washington Street, Boston, Mass., or James Potter, District Passenger Agent, 833 Chestnut Street, Philadelphia, Pa.

THE TREATMENT OF INGUINAL HERNIA.*

ALEX. DALLAS, M.D., New York.

No subject has come before you, at this meeting, of greater importance than that of Hernia. From the frequency of its occurrence; from the universality of its prevalence, invading, as it does, all ages and conditions of society; from the pain and discomfort to which it gives rise; from its disabling effects, debarring its victims from many avenues of livelihood and compelling them to a quasi-invalidism; and from the large number of deaths directly due to it, and the still larger number traceable to its depressing and debilitating effects, the proper treatment of hernia forms the most important branch of practical surgery.

Now, the aim of all surgery is to relieve suffering and remove disability or deformity: and no other surgical disease is so frequent or gives rise to the same amount of pain and disability, while few exceed it in mortality. As a conservative estimate, there are to-day, in this country, *three and one-half millions* of persons suffering from hernia, *a ratio of thirty cases of rupture to every practising physician*. This, surely, proves the absolute necessity there is for every practitioner to make himself familiar with the treatment of hernia and to be prepared to meet the sudden and dangerous complications to which it often gives rise. No physician has the right to carelessly delegate to others duties for which he alone is qualified, and for the proper performance of which he should be accountable. Correct methods of treatment are within the compass of every practitioner and, during the short time at my disposal, I shall briefly present those which have proved most satisfactory in my hands. These methods may be divided into 1st., "the palliative;" 2nd., "the mixed;" 3rd., "the radical; 4th., "the treatment of strangulated hernia."

THE PALLIATIVE.

The palliative treatment of hernia includes all measures used to prevent the descent of the hernial protrusion, such as the recumbent posture, bandages, but more particularly, the employment of trusses of various descriptions. It is of the utmost importance that palliative treatment should be commenced as soon as a disposition to the formation of a hernia is detected; for, by the prompt initiation of treatment, and its judicious continuance under the personal supervision of the surgeon, cures can often be effected where failures are now the rule. Particularly important is this fact in the hernia of childhood where palliative measures are, of themselves, sufficient in almost all cases to effect a cure: and to permit a child to grow up to adult age handicapped by so serious an infirmity, bespeaks culpable neglect or criminal ignorance.

Success in the treatment of these cases can only be attained by prompt, intelli-

*Read before the New York State Medical Society, Albany, N. Y., February, 1893.

gent, persistent effort on the part of the surgeon and attendant; and the absolute necessity for skilled supervision cannot be too strongly urged upon the laity by the profession.

Unfortunately, many practitioners act as if truss-treatment were of little consequence and beneath their dignity or, as a prominent surgeon of this town put it, "work for a blacksmith." These men will spend hours over a fracture which almost any neophyte can diagnose, and on the application of a splint which is only temporarily required, while they carelessly delegate to the druggist's apprentice or the truss vendor the adjustment of a truss upon which the welfare and life of the patient depend. On the other hand, the truss dealer is careful to inform the patient of the doctor's inability to cope with these cases through his ignorance of the subject. A prominent truss dealer in New York who depends entirely upon the physicians for his business, assured me that "not one doctor in one hundred knew enough to take the correct measurements for a truss." And the physician wonders what has become of his patient! The lamentable results of this evasion of duty are witnessed daily; for the trusses generally employed prove veritable implements of torture, causing irreparable injury and life-long misery. Too weak, they allow the rupture to descend and become bruised and compressed; too strong, they cause absorption of the parts against which they press; ill-shaped and wrongly adjusted, they contuse important organs; and the blame of all this is placed upon the rupture, where it does not belong, but upon the physician who shirks his duty and the tradesman who is unfit to assume it. Neglected and discouraged by the physician, illtreated and tortured by the tradesman, is it any wonder that these poor sufferers fall ready victims to the charlatan with his wonderful ointments and lotions and his guaranteed cures?

To select a truss with judgment, the surgeon should familiarize himself with the instruments now in use and acquaint himself with the advantages claimed for each. On his selection and subsequent care will depend the success or failure of the treatment, and the comfort or misery of the patient. The requisite and essential qualities of a good truss are as follows: It should be light, so as not to burden the patient; strong enough to prevent protrusion; elastic enough to follow the abdominal movements; firm enough not to be easily displaced; so arranged that it does not press injuriously upon important organs nor interfere with the movements of the body; and so adjusted that it fits like a well made garment. To make effective pressure, there must be a firm point of support from which to make it; there must be a back pad as well as a front pad. In this way we secure greater accuracy with less pressure. Each hernia should have the truss specially adapted to it; the pad and the spring should be regulated by the case. It should be inspected at regular intervals and the pressure increased or diminished as the case may demand. And the surgeon should remember that, after the unavoidable inconvenience of the first few days, *any further pain or discomfort is unquestionably due to an ill-adjusted or improperly made truss*, and its continuance is unnecessary cruelty.

A careful examination of the trusses now in use will readily show how imperfectly they meet these indications. In all, the spring passes around the buttocks and rests upon the gluteal muscles. As a result, the pressure is applied laterally and, therefore, at a disadvantage, while, in most, it is unnecessarily severe. Naturally, the instrument moves with every motion of the body, producing painful excoriations of the skin. They all impinge upon the pubic bone and thus increase the discomfort of the patient. The shape of the ordinary pad is an anomaly and its method of application unscientific. Its conical surface, driven into the external ring by the powerful spring and kept in constant motion by every movement of the body, bores its way into the canal and actually enlarges it; while the severe pressure which it exerts causes atrophy of the surrounding tissues. In all, their point of greatest pressure is at and below the external ring where there is only integument between the pad and the pubic bone. As an inevitable result there occurs compression and gradual occlusion of the spermatic cord. With the present truss this is *unavoidable*, and the injury is *direct and positive*. From this source alone come the pain and misery of which so many complain and which gradually induce a nervous irrita-

bility and lowered vitality which render the sufferers easy victims of any intercurrent attack. A ready proof of the correctness of this statement is furnished by the result of the removal of the pad from the pubic bone when all these symptoms disappear.

The employment of flat pads, as is found in some trusses, intensifies the pressure at their lower borders and they should never be used in inguinal hernia. The so-called elastic truss should, under no circumstances, be employed. By the use of the tight perineal band, the pad is firmly pressed down upon and anchored over the pubic bone, causing injurious pressure upon the cord, while the constantly retracting action of the rubber band produces atrophy of the tissues on which it presses.

In all these trusses the pressure of the pad upon the external ring is upward and backward *causing pouting of the abdominal end of the canal,* thus predisposing to the presence of a *bubonocele.* This upward pressure is intensified in the "lever truss," and the pain and injury are also greater. The "cross body" truss, highly endorsed by some, is particularly objectionable; for the incessant motion to which all side springs are subjected is here increased on account of the greater length of the lever.

An effort is sometimes made to overcome this tendency to drop by increasing the size and convexity of the pad and the strength of the spring, but the truss soon sinks down until it rests upon the pubic bone. The receding abdominal walls, the constant motion to which the instrument is subjected and the force of gravity are obstacles too great to be overcome.

The truss I now show you is the result of years of experiment and, during the time it has been in use, it has seemed to meet the requisite indications. It is light and cool. It rests upon the crest of the ilium, an immovable support, and is not affected by any of the movements of the body. There is no constricting band around the hips to cause atrophy of the muscles and to interfere with every motion. As a result, there is no incessant disturbance of the pad and, consequently, no excoriations to heal up. The belt passes down the sides of the abdomen closely hugging the abdominal walls, thus breaking the lateral recoil of the intestines which causes the protrusion, and acting as an auxiliary to the pad. The pad, itself, of hard rubber, is small and somewhat quadrilateral in shape; its lower outer angle cut off to fit into the fold of the groin; its surface flat or slightly concave to adapt itself to the convex abdominal walls. Running from the centre of the face of the pad to its lower edge is *a gradually deepening groove* which *prevents compression of the spermatic cord.* The pressure exercised by this truss, being applied from above downward, is slight, comfortaby borne and directly over the *internal ring* and *upper part* of the canal; and *it is the only truss by which pressure can be retained there.* Another important feature is its ease of application. Once properly adjusted, it can be taken off by the patient and reapplied without fear of displacement, a fact which cannot be said of any other truss with which I am acquainted. As all spring trusses should invariably be removed at bedtime, to be reapplied on getting up, the importance of this will be readily appreciated.

The benefits to be derived from truss pressure should be thoroughly understood and are purely mechanical. By keeping the sac entirely empty and preventing the intrusion of the gut, the sac, with the surrounding tendinous ring, contracts, in obedience to the general law by which all hollow parts of the body adapt themselves to their contents. In *congenital* hernia, the exclusion of all foreign bodies from the vaginal process of the peritoneum permits of the contraction and obliteration of the cavity which would otherwise naturally have occurred. In *acquired* hernia, before the sac has attained a a separate existence of its own, the pressure of a properly adjusted truss restores the peritoneum forming the sac to its natural situation, the cavity of the sac is effaced and the peritoneum recovers its former polish and elasticity. In this way, cures sometimes take place in adults, but can hardly be expected in old people. When the sac has acquired an independent existence, the action of the truss is still purely mechanical. By preventing the entrance of gut or omentum it places the parts in the most favorable condition to undergo those changes of gradual contraction and obliteration described elsewhere. In all cases successful results can only be attained by a careful adjustment of the amount and direction of the

pressure in each case and a constant supervision during the progress of the treatment. If too little pressure be employed, the bowel, but especially omentum, will be constantly slipping down and getting compressed and a cure can never be effected. If, on the other hand, too much pressure be used, particularly if the usual *conical pad* be employed, the opening gradually enlarges and the surrounding tissues atrophy.

When the truss has been applied the medical attendant seems to think that his work is done. As a matter of fact, the real treatment of the case has just commenced if he expects to obtain a cure. The patient should be kept under the surgeon's supervision and should be carefully examined at regular intervals to assure himself of the perfect retention of the hernia, as well as in the case of children, to provide for their rapid growth. Perfect cleanliness should be preserved and all causes that operate to prevent or retard nature in her efforts at repair should be removed. The digestion should be carefully looked after. Constipation should be prevented. Vomiting or straining from any cause should be avoided, as well as excessive bodily exertion, and, where the patient is obliged to make any considerable effort, he should be taught to support the pad with his hand. The persistence of any of these causes may hinder, or even completely destroy, all chances of cure directed solely to the hernial protrusion.

At the same time, efforts should be made to develop and strengthen the weakened tissues by massage, electricity and gymnastic movements of various kinds. *No spring truss should ever be worn in bed.* In most cases it is unnecessary; in all it is harmful. When it is considered desirable to have some support, as in children, the truss should be removed at bed-time and replaced by a "hank truss" or home-made bandage.

What results can be expected from prompt, careful, judicious, persistent, palliative treatment? In infants and in children up to puberty, a cure should be expected and can be obtained with scarcely an exception. In adults, if treatment be commenced immediately on the appearance of the first symptoms, or before the sac has formed, success can often be attained; but cases of epiplocele are less likely to be cured on account of the difficulty of keeping it reduced. (The crural ring, also, from its structure and situation, is less affected by external pressure than the abdominal ring. Crural hernia, therefore, is less frequently cured than inguinal, for the sides of the aperture appear less capable of contraction and, certainly, less susceptible of approximation from external pressure.) In old people, we cannot look for a cure, but proper treatment will prevent any increase of the hernial tumor.

MIXED TREATMENT.

When, after a fair trial, the palliative method of treatment has failed, other measures have at various times been tried, but the uncertainty of their action and the temporary character of their results have caused them to pass into disuse. To obviate these difficulties I have devised an instrument which is applicable both in inguinal and femoral herniæ. It is simple in its application; it is definite and exact in its results. It is entirely free from danger and the confinement necessitated by its employment is of short duration. The patient's consent can be readily obtained and its use can be safely recommended in all suitable cases. Finally, its results will compare very favorably with those of other and more dangerous measures. The instrument consists of a head and shaft or handle. The head is flattened and its point smooth and blunted. Its anterior and posterior surfaces and outer edge are covered with fine needle pointed projections while its inner edge is smooth and occupied by a deep groove. The cover of the shaft is movable and, while the instrument is being introduced, is pushed forward so as to cover completely all the serrations and present a perfectly smooth, rounded surface. In operating, the parts are prepared in the usual way, while the instrument is rendered thoroughly aseptic by boiling. Twenty or thirty drops of a four per cent. solution of cocaine is injected into the field of operation and a transverse incision, one inch long, is made through the integument, just below the external ring. The fascia is carefully separated and the spermatic cord gently lifted towards the inner wall of the canal. The instrument is now introduced, the groove turned towards and embracing the cord, and cautiously insinuated through the canal until its point is felt

free in the abdominal cavity. The shield is now removed and the instrument slowly withdrawn, during which the whole interior surface of the canal, except the portion covered by the groove, is abraded and freshened. The surfaces are pressed together as the instrument is being withdrawn so as to prevent any unnecessary effusion of blood; the external wound is closed and sealed with iodoform collodion; a firm compress is placed over the canal and retained in position by strips of plaster and a bandage, and the patient is kept in bed for a few days until all local tenderness has passed away. By this simple method, we at once secure complete agglutination of the walls of the canal and, consequently, a firm and permanent cure, without pain and with only three or four days confinement to bed. A light truss, with a grooved pad, is then adjusted and the patient allowed to go about. At the end of two or three months, the truss can be discarded, the measures already described being used meantime to strengthen the parts.

This operation is applicable in all recent cases of acquired inguinal and femoral hernia and in all cases of congenital hernia, even of long standing. (It can be used in any case where the canal has not become obliterated by the pressure of the protruding viscera.) In femoral hernia the incision is made over the saphenous opening, the groove is turned towards the femoral vein and, in the after-treatment, the leg should be well supported.

In the cases in which I have used it the results have been most satisfactory and entirely successful.

By the early and judicious employment of these two methods much good may be accomplished and the necessity for radical interference can, in the future, be largely limited to long-standing tumors of large size, associated with adhesions or other complications.

RADICAL.

After failure of the milder measures already described the advisability of resorting to the so-called "radical cure" may be entertained. It is too much the custom, nowadays, to resort to cutting under any and all circumstances, but it is well to remind enthusiastic advocates of promiscuous operating that the "radical cure" operation is, under the most favorable circumstances, a serious one; that it jeopardizes the patient's life, and that the results are not always commensurate with the risks incurred. Statistics are quoted to show the harmlessness of the modern operation giving a mortality ranging from two to five per cent., according to the skill of the operator and the ingenuity of the reporter, but even these results are only attained by the greatest skill and under the most favorable conditions. If the operation, in all cases, effected a "radical cure" and relieved the patient of the often intolerable encumbrance of wearing a truss, its performance, even though dangerous, would be perfectly justifiable, but there is no reasonable assurance of certainty even in this. It should never, therefore, be lightly resorted to, nor its acceptance urged upon the patient without proper cause. On the other hand, though its performance may not be free from danger and a "radical cure" may not be obtained, so much benefit can be secured by a properly selected operation as to fully justify resort to it under certain well-defined conditions.

In deciding, therefore, upon the advisability of resorting to the "radical cure," each case must be considered on its own merits. The health and age of the patient, the size of the tumor, the risk incurred, the incapacitating nature of the hernia, the danger of strangulation, the distance from efficient medical aid, the inconvenience and expense of obtaining proper trusses, are all features which must be taken into account. So, also, are the local complications such as irreducibility of the protrusion, non-descent of the testicle, the supervention of a hydrocele or varicocele, and the dangers from external injury. All these increase the patient's risk, and the greater the severity of the inconvenience, pain and danger endured, the more prudent it will be to endeavor to remove them by operative interference. So, also, in irritable natures, the worry of unsatisfactory truss pressure removes the slender possibility of a cure by this means and often renders life a burden, deteriorating the constitution so as to predispose it to tendencies which shorten life. The wishes of the patient must also be considered in deciding upon the question of operative interference.

Numerous methods have at various times been employed to obtain a "radical

cure" and new ones are appearing every day, but, even now, there is not one which commands the respect of any considerable body of the profession. This is mainly due to the fact that no two agree on the essential objects to be accomplished and the best methods of securing them, as well as to the unsatisfactory results obtained. A careful study of the different steps in the formation of an inguinal hernia will indicate the only method by which the injury can be repaired. The first step is the bulging or giving-way of the parietal peritoneum, the sac of the hernia. Unless checked this gradually insinuates itself into the opening in the *transversalis fascia* forming the internal ring, causing a gaping or pouting of the lower lip. The hernial tumor then forces its way through the canal displacing the tissues of which it is composed, particularly the outer wall of the canal and, finally appears at the external ring. The indications to be met to insure success are: First, the restoration of the peritoneum to its normal condition as near as possible, so as to permit of the free gliding movement of the bowels over its surface. To accomplish this the sac should be freed from all adhesions, the peritoneum loosened for some distance around the internal ring and gently pulled down, and the whole length of the sac should then be cut away, not only to obliterate the depression on its surface, but to remove every portion of peritoneum which has become more or less altered from stretching. For the same reason the cut surfaces should be sutured together so as to present as smooth a surface as possible. When tied in a ligature there is more or less puckering which resists the free movements of the bowels over its surface. Second, the pouting of the lower lip of the internal ring should be obliterated so as no longer to invite intrusion of the bowel while the displaced external wall of the canal should be approximated to the inner wall the better to support the peritoneum and transversalis fascia. This can be accomplished by passing two sutures parallel with the outer line of the canal, as in the MacEwen operation, the upper one including the lower edge of the internal ring. In large herniæ, where the whole external wall is displaced, it would be well to insert two sutures in the same way along the inner line of the canal. In large old herniæ, where the internal ring is much dilated so as to be opposite the external ring, it will be necessary to freshen the hardened edges of the ring and suture them together with a continuous double suture. Every step of the operation should be done under the strictest antisepsis; all dead pockets should be avoided as they serve only to collect blood and serum; drainage tubes should not be used and every effort should be made to secure healing by first intention as it materially increases the prospects of success.

To be effectual and permanent, therefore, the operation must produce *obliteration* of the *hernial sac, closure* of its *ventral orifice* and *strengthening* of *those weak parts* in the abdominal parietes through which the rupture protrudes. At the same time measures must be taken to produce an improved tone of the general system, particularly of the peritoneal ligaments of the viscera, by which the power they exert in retaining the organs in their normal position is restored. The more this is accomplished, and the closer the processes of nature are imitated, the more perfect the result, but no operation can be considered a "radical cure" that does not enable the sufferer to dispense with the use of a truss.

STRANGULATED HERNIA.

The usually sudden onset of strangulation, the immediate development of constitutional symptoms of a most dangerous and characteristic nature, the mental anxiety and alarm of the patient, together with the intense pain from which he suffers, and the consciousness that, on his judicious management of the case depends the life of the patient, invest cases of strangulated hernia with an interest and importance to the surgeon which cannot be over-estimated and which demand consequently the most careful study and attention. Measures, therefore, for its reduction should be immediately adopted and should be persisted in until relief has been secured. Many lives are sacrificed every year by improper treatment and delayed interference. To the patient delay is highly dangerous; in the surgeon, indeed, it is criminal since every hour of strangulation adds to the risk which it is his duty to diminish.

Various methods have been used at dif-

ferent times to obtain relief, but, at present, the three great means on which surgeons consecutively rely to secure reduction are anæsthetics, taxis and herniotomy. Other adjuvants are also advocated.

Now the adminstration of an anæsthetic requires the presence of an assistant, and invariably produces more or less depression; while its long-continued administration is never free from danger. It is generally followed, also, by more or less vomiting and it is sometimes difficult to know whether the persisting vomiting is due to this, or depends upon imperfect reduction of the hernia.

As ordinarily used the employment of taxis is extremely hazardous. All authorities agree that the frightful mortality which now exists in cases of strangulated hernia is directly attributable to violent, ill-directed and protracted taxis and to the consequent delay in operating. Many act as if taxis consisted in directed violent pressure; it is in reality a combination of grasping, compressing and kneading which can only be acquired by long experience. When resorted to it should always be used with the greatest gentleness and for very limited periods. I believe that it should never be used for more than five minutes at a time and never more than twice. On failure of a second attempt, herniotomy should be immediately resorted to. There is a period when taxis is not only dangerous but inadmissible. When evidences of gangrene are present or threatening, when fecal vomiting has lasted for several hours with hiccough and symptoms of collapse, the use of taxis is positively contra-indicated. Even after twenty-four hours strangulation there is great danger of rupturing the bowel if the taxis be violent and prolonged. This is especially true of small, recent enterocele, particularly of the femoral variety.

Cold, in the shape of ice bags, etc., is strongly recommended, but it should never be used. Its application endangers the vitality of the already enfeebled tissues. Hot applications, on the contrary, can be used with safety, and are far more agreeable and beneficial to the patient.

Ether irrigation has been in vogue for several years in reducing strangulated hernia. Finkelstein, its chief advocate, claims to have succeeded in fifty-three per cent. of enterocele; but, in epiplocele, he admits it is of no value.

Even in the hands of experts the results of all these measures are unsatisfactory; hence, a method of treatment which is free from the disadvantages and dangers of those now in use, which is so simple that any one can use it, and so successful that all cases yield to it, must commend itself to the favorable attention of the profession. For fifteen years it has been under test, and, so far, there has not been a single failure. The patient is placed in the recumbent position, the hips raised, the knee bent on the body and the tumor supported. A hypodermic injection of morphia $\frac{1}{4}$ grain, atropia $\frac{1}{120}$ grain, cocaine $\frac{1}{8}$ grain, is at once given in the neighborhood of the rupture and repeated every fifteen minutes until the patient is comfortable. Meantime he *is made to drink* every five minutes from two ounces to four ounces of a *hot* mixture consisting of strong black coffee one pint, fluid extract of Ergot two and four drachms, and when the pulse is weak and compressible, strychnine $\frac{1}{30}$ grain. At the end of half an hour the rupture has become flaccid and disappears, or gentle manipulation reduces it. I have never had to give the second dose, nor have I had to wait over half an hour to secure reduction while the necessary manipulations never exceeded two minutes. No anæsthetic was ever used or required. If, however, there should be no change in the tenseness of the tumor the same quantity of the mixture should be given during the next half hour and, if reduction cannot then be effected, the knife should be at once resorted to.

The advantages of this method of treatment are obvious. By the injection the pain and distress are at once alleviated and confidence inspired, an important item in these cases. At the same time gastric irritability is allayed and vomiting becomes much less frequent or even ceases while the muscular tissues, freed from irritation, become relaxed. The fact that no anæsthetic is required is a decided advantage, for it prevents the employment of excessive and long-continued taxis and the injuries arising from it. At the same time it obviates the depression which its administration causes. The amount of taxis necessary for the reduction of the hernial tumor, after the administration of this mixture, is so slight and of such short duration that no injury can be inflicted upon the contents of the sac and

reduction *en bloc* is impossible; while, if operative measures are immediately resorted to, on failure of the second attempt, no unnecessary delay will be incurred and mortification of the bowel will become a rarity.

The fatal delay in resorting to operative interference is mainly attributable to the fact that many medical men do not seem to realize the dangers incurred by a continuance of the constriction and look upon the operation as a last resource, and they will not consent to its use until death is imminent. The operation itself is not a dangerous one; the condition that demands it is exceedingly so. Its performance, indeed, is harmless compared to the danger incurred by allowing the constriction to continue. Many have to deplore its performance too late; no one regrets resorting to it too soon.

These are the views I hold on the treatment of hernia and which I now submit to your kindly criticism. They are simple and within the compass of every practitioner. In my hands they have proved eminently satisfactory and their general adoption would greatly alleviate the sufferings and materially reduce the mortality amongst the victims of hernia.

SURGICAL MEASURES OF RELIEF IN STENOSIS OF THE UPPER AIR PASSAGES.*

THOMAS H. MANLEY, M. D., New York.

During the past ten or fifteen years the discussion of the etiology, pathology and surgical treatment of stenosis of the ærial passages, particularly in children, has occupied an important position in medical literature, both home and foreign.

Yet, with all that has been written on this subject, it must be admitted that the profession is in anything but accord on the most appropriate measures, either prophylactic, or remedial, in those maladies which jeopardize life through impending asphyxia or apnœa.

It was hoped with the application of the invaluable apparatus of Dr. O'Dwyer that, at last, the most formidable obstacles in the way of treatment had been forever removed; that the scalpel and tracheal tube might be laid aside, and that hereafter relief-measures would be as prompt and bloodless as they were efficient and permanent.

But it was soon discovered that, like every other relief measure, intubation has its limitations; that there is a considerable proportion of cases in which the perforated, laryngeal plug may, when introduced, destroy every possible prospect of recovery. Our aim should be, in all cases, to occupy a middle ground; as neither too zealous partisans of the one, nor uncompromising foes of the other. Some would impose so far on the credulity of their brethren as to have them believe that intubation is the sovereign remedy when applied early and skillfully. Others there are, who have cast it aside altogether. Of this latter I saw a practical proof in the Princess Augusta's large ward for children in the Frieriechshal-Hospital, in Berlin. Here their experience with intubation had been so unfortunate that they had discarded it altogether. Hence, while we all agree that divulsion of the laryngeal chink through the buccal cavity occupies an important place in surgical therapy, it constitutes but one of our resources. In the controversial side of the question, it is not my purpose, at this time, to enter.

The conditions that give rise to a mechanical impediment to respiration in the upper air passages are dependent on inflammation—infectious, specific, neoplastic and traumatic.

The fundamental principle underlying every phase of treatment, of whatever description instituted, is to secure a patent air-passage until nature has removed the barriers to normal respiration. To most safely accomplish this purpose we must depend chiefly on three agencies: First, on constitutional treatment, which is more or less applicable in all phases of laryngeal stenosis; second, on local medicative measures; third, on surgical invention.

*Read before the Section of Pædiatry, Academy of Medicine, New York, Feb. 9th, 1893.

As the surgeon's aid is seldom invoked until the time is past for internal medication, only the second and third of these agencies will be considered here.

For the first of them, there are but two substances with which I am acquainted, that possess such properties as will commend them in the majority of cases. I may add parenthetically, that unless the patient is on the border line of the moribund state, local measures should be pressed with energy for a short time before surgical intervention is resorted to.

Mercury pre-eminently occupies the first position. First, because of its well-known power as an antiseptic agent; and secondly, for its effects on the general system when taken up by absorption through the mucous membrane. It may be administered by fumigation—when calomel is incinerated; or through the spray—where we employ the bichloride solution of a strength varying from 1:500 to 1:3000 according to the age of the patient, its impression on the system, or the urgency of the symptoms. The objections to its employment are the possibility of ptyalizing the patient or salivating the nurse or attendant. Besides, though this agent possesses active bactericidal powers, it is not a deoderizer.

In many cases of an infectious or gangrenous character extending into the larynx or trachea, the ideal solution is one which is gentle and simple in its application, but energetic in action; one best tolerated and possessed of the greatest affinity for the necrotic residue of diphtheritic or other inflammatory products. To attain this end there is nothing with which I am familiar, which may be administered so continuously as the peroxide of hydrogen.

An eminent medical authority* has recently warned the profession not to use this agent in throat troubles, because, as he alleges, it may cause diphtheria itself. This view is totally at variance with clinical experience and with our knowledge of the fundamental etiology of this disease; though we must concede, if an inferior quality of the chemical is used, or it is employed in too strong solution, an exudate is formed, but this exudate must be rather attributed to its injudicious employment than to any inherent power of the drug to produce such exudate. In all cases, when we employ this gaseous agent we should be assured of its purity and standard strength; hence it is my custom to employ Marchand's medicinal, alone, when it can be secured. The inhaler which goes with this medicament, in my hands, in the hospital and elsewhere, has served an admirable purpose in pharnygeal or laryngeal affections. "The immense number of unsophisticated medical men all over this country whose anxiety is for new and effective remedies, and who are stimulated by these miserable surroundings"† may be safely trusted with the best and safest in the matter of chemical solutions, as in the selection of wines, meat juices, proprietary medicines or other pharmaceuticals.

When it appears futile to persist further with local applications, and the symptoms of approaching asphyxia are urgent, the time has arrived for prompt surgical interference. It is well known that in tracheotomies the results following, depend mainly on two factors, viz: the violence of the constitutional infection, and the manner in which the operation for relief is performed. The former is beyond our control, but not so with the latter. For, with the aids that modern surgery has placed within our reach, the technique of opening the air passages above the sternum has been greatly simplified. The elder Gross regarded tracheotomy as one of the most formidable operations known to surgery.

The dangers immediately connected with the surgical technique of a tracheotomy are:

(1) Those which have reference to pulmonary anæsthesia.

(2) Hemorrhage.

(3) Shock.

With every one who has ever administered an anæsthetic, or seen it given to one with an embarrassed respiration, it is needlessly to rehearse here the difficulties in the way. In the first stage of anæsthesia the little one violently struggles and strangles so that the anæsthetizing agent must be given intermittently. As the second stage of anæsthesia is reached a deep cyanosis sets in. With the accession of the third stage the corneal reflexes are paralyzed and the asphyxia deepened so

*Dr. A. Jacobi, Note on Peroxide of Hydrogen. *Archives of Pediatrics*, Dec., 1892.

†Ibidem.

that the operator is warned to hasten on or death will quickly end the scene. But our patient is a child, and it is a matter of common observation that children, proportionately to their age, take a large quantity of anæsthetics and come from under their influence very quickly. Hence, under the circumstances here considered, the circulation already toxemic must be further super-saturated with another lethal agent, and along with this, the fear of the patient's returning consciousness hurries the surgeon on with the procedure in which it is always imperative to proceed with caution and deliberation. Anæsthesia is, it must be admitted, one of the positive dangers in opening the trachea.

Without question the next difficulty in this operation is profuse hemorrhage. Here the escape of blood is dangerous in a dual capacity. First, through mortal anæmia, and next through leakage into the trachea inducing fatal asphyxia, or by being sucked into the bronchial radicles and causing septic pneumonia. As the trachea in the child is deeply lodged beneath an immense network of blood vessels which lie immediately under the skin, the deep cervical fascia and over the thyroid isthmus, the division of the deeply situated parts is not unlike the splitting of a saturated sponge. Nevertheless, if ample hæmostatic precautions are observed, after the first gush in penetrating the deep cervical fascia, it will be slight and will neither annoy the operator nor endanger the patient.

In May 1890, Paul Réclus, in the *Gazette Hebdominaire*, published his remarkable contribution on "Cocaine analgesia." The year preceding, Prof. W. W. Dawson had presented an able essay entitled "Bloodless Tracheotomies."* Although Réclus reported more than two hundred cases in which he had successfully operated under cocaine, he mentioned none for tracheal stenosis. After I had carefully read the essays of the both the Ohio and the French surgeons, it occurred to me that, by a combination of both expedients, the ideal tracheotomy operation was at last secured. Within one month of the publication of Réclus' essay I was favored, at the Harlem Hospital, with an opportunity of testing for the first time, and estimating the full value of, a surgical procedure which I have designated "Tracheotomy by the Réclus–Dawson Method."

I, personally, claim nothing for myself in connection with this invaluable device, save in evolving a new operation by a combination of analgesia with hæmostasis, and priority in being the first to operate by this method and to publish its history and technique. This I did in the *Journal of the American Medical Association*, September, 1891.

Though I have had four opportunities of employing it in the adult, up to this time I have had but one child, an infant, on which to test its merits. This was a patient of Dr. Murray's, but two months of age, which was suffering of submucous tubercular abscess of the larynx. All my patients recovered.

In a nutshell, its technique is as follows: Rigorous antisepsis; a one per cent. solution of hydrochlorate of cocaine hyperdermically administered after Réclus' plan; the drug hypodermically employed, never to exceed the maximum dose by the mouth. I always douche the surface of the integument, either by a spray from a siphon of carbonated water, or else pour cold water from a height, which accomplishes the same end, before I make the first incision. The cocaine injection serves a triad purpose in these cases; first, as an analgesic; secondly, as a cardiac stimulant, and thirdly, as a styptic or hæmostatic. In these cases which we tracheotomize for infectious or acute inflammatory obstruction, and in which patency of the opening is but a temporary expedient, I am confident that the best tracheal tube is none at all. In this infant of two months, by passing two sutures through the divided tracheal walls on either side an ample air vent was effected.

I am confident that as the new procedure is more generally adopted, tracheotomy will regain its lost ground. For by it, when it succeeds, deglutination is not interfered with, perfect drainage is secured and the inconvenience and danger always attendant on tubation of any description, is obviated. It is unnecessary to add that by it, too, the dangers of collapse and shock will be minimized.

CLINICAL LECTURES.

PNEUMONIA: GALL STONES.†

JOHN A. ROBISON, A. M., M. D., CHICAGO.*

GENTLEMEN: The first case I show you is a night switchman, who has been exposed to the frequent changes of weather that occur during the night, and more especially to the dampness of the Chicago climate. On the 21st of December he was awakened in the afternoon about 4 o'clock with a severe chill. He sleeps in the day time. This chill lasted for some hours. He had pain in the right side centering about the region of the nipple, and radiating from that region. This was followed by a high fever and within twenty-four hours a cough supervened. In about four days thereafter he began to expectorate a bloody tinged sputum. He went through probably the first and second stages of pneumonia, and was brought to the hospital on January 6th. At the time of admission his pulse was 114; temperature 101.8°; respiration 44. This was at 6 o'clock in the evening. At midnight his pulse was 104; temperature 101.2°; respiration 52. Upon examination we found consolidation of the upper lobe of the right lung, there being slight loss of motion on inspection and slight dullness of percussion; bronchial breathing and bronchial voice. The expectoration was characteristic of pneumonic inflammation. The next day, in the evening, his pulse was 96; temperature 99°; respirations 40. The next morning at 4, pulse was 72; temperature in the axilla 97.8°; respirations 32. At midnight pulse was 88; temperature in axilla 99°; respirations 24. The next day, at 1 A. M. temperature was 98.6°; respirations 20. Since that time he has had no rise of temperature; his pulse varies from 72 to 80, and respirations from 20 upward.

The case arrived at the hospital during the stage of convalescence. It would be interesting to have a complete history of this case from its inception. His symptoms were first a severe chill, then pain of the part affected and high temperature for seventeen days. He had the lysis before the seventeenth day, and then a crisis on the seventeenth day. In pneumonia there is generally a high fever from four to twelve days, then it lessens by lysis or drops suddenly by crisis.

The stage of convalescence is well established in this case and there are few physical signs. The evidences by inspection are *nil*. There is no cyanosis; his respirations are normal; there is no loss of motion on either side, and the dullness has almost entirely disappeared. I have drawn a line down to the point where dullness disappears. If you percuss from the apex downwards you will notice dullness until you reach this line, below that you get normal resonance. I have marked this point where we get pronounced bronchial breathing and bronchophony. He still expectorates a sputum slightly tinged with blood and purulent in character.

The treatment in this case has been the ordinary treatment by the cotton jacket and the giving of easily assimilable nourishment. On admission he was placed on five grain doses of muriate of ammonia with half an ounce of whiskey every four hours. Two or three days afterward he was placed upon the iodide of potash, two grains three times a day; for tonics, iron and strychnia. The iodide of potash was given as an alterative and also to facilitate expectoration, and the tonics to promote nutrition.

GALL STONES.

This patient was admitted to the Presbyterian Hospital on the 30th day of December. She is 34 years of age, American by birth, married, has had three children, previous history and family history both good. The present illness followed an attack of typhoid fever in November 1891, the typhoid fever lasting 13 weeks. From that time till the last of September the patient had not been in very good health. The present illness commenced with itching all over the body—no pain—followed

†Delivered at Rush Medical College, January 12th, 1893.

*Attending Physician to Presbyterian Hospital; Professor of General Medicine, Post Graduate Medical School; Adjunct Professor to Chair of Practice of Medicine, Rush Medical College, etc.

by an icteric discoloration of the skin. She also had diarrhœa, with fever. The stools were clay-colored. The eruption over the surface of the body first resembled the scarlet fever eruption. She has also had previously two attacks of colic due doubtless to gall stones. On admission to the hospital she was intensely jaundiced. Over the region of the gall-bladder or duodenum there is quite an amount of tenderness.

We have here a case that may be either a catarrhal inflammation of the gall duct or of the duodenum, or, it is more likely, a case of impacted gall-stones, because she has had several attacks of colic which seemed, at the time to be induced by gall-stones. These gall-stones enter the ductus choledochus and lodge there, producing the attacks of colic, jaundice and tenderness over the region of the gall bladder. An operation for the removal of gall-stones is the only radical treatment, and this leads me to speak of the uselessness of giving medicines that have an alleged solvent action on biliary calculi.

A few years ago I was called to see a case of impacted gall-stones where the patient, a lady of middle age who had been an invalid for several years and was just recovering from the results of an operation for abscess of the right kidney by our late lamented Professor Parkes, was suffering intensely from pain, intractable vomiting, and localized peritonitis. Her family physician was summoned from the country resort where he had gone for recreation and a surgeon was called in counsel. There was no difference of opinion as to diagnosis, but an operation was deferred until medical treatment could be tried further. The result was the patient soon died, and the autopsy demonstrated that an operation would have relieved the suffering, if not saving the patient's life. There was an adhesion between the gall-bladder and parietal peritoneum, and several gall-stones were found impacted in the gall-bladder, and in the ductus choledochus a very large stone was found lying adjacent to the hepatic artery, and ulceration of the wall of the artery had taken place from pressure until there was almost a perforation into the artery.

On admission this patient was placed on five-grain doses of chloride of ammonium. The reason for giving it, it is supposed to be efficient in gastro-duodenal catarrah, or in a catarrhal inflammation of the bile ducts. Recently she has been placed upon five to ten-grain doses of benzoate of sodium, to lessen the jaundiced condition of the skin. It has been combined daily with hot alcohol baths, producing a large amount of perspiration. I think there has been improvement in the condition of the patient. The bowels move daily, the appetite is good, and the color of the skin is better.

If this patient should have any recurrence of colicky attacks, cholecystectomy will be performed.

COMMUNICATIONS.

SOME INTERESTING OVARIOTOMIES.*

L. S. McMURTRY, M. D., Louisville, Ky.

Some years ago Mr. Tait said that the last words had been uttered on the subject of ovariotomy; that there was nothing more to be said; that the mortality was reduced to the least of any major operation known in surgery, which is true. But ovarian tumors are so common and present such a diversity—dermoid, parovarian, multilocular and poly-cyst, etc., with their variations and complications—that they prove of continuous interest.

In the first place in regard to ovariotomy in the aged, there are very few major operations that any of us like to undertake in very old subjects, operations where there will be a very heavy strain on the system, great danger of shock, and where there will be a great deal of traumatism to vital organs in connection with the operation; all dangers are very much exaggerated in the aged.

*Read before the Clinical Society of Louisville Jan. 10, 1893.

Last October I operated for a very large double ovarian cyst in the case of a lady from Kansas, seventy-two years old. The tumors were so large (I only suspected one tumor when beginning the operation) that they extended to the diaphragm; abdomen distended so that the skin was shining, the umbilicus pouting and the condition of the woman was distressing. She said that her journey from Kansas to Louisville was the most trying ordeal through which she had ever passed. The operation disclosed very extensive intestinal and bladder adhesions which are always difficult to deal with, especially so in cases where they are old and firm. The pedicle of the large tumor on the left side was one of the largest that I have ever dealt with; it had to be quilted with a double ligature and another ligature around. The patient made a smooth and easy recovery.

Another case, referred to me by Dr. J. M. Krim, is a lady who will be seventy-two years old in March. When I first saw her with Dr. Krim, we made diagnosis of ovarian cyst as most probable, although neither he nor I could say positively that it was ovarian because we could not get any fluctuation of the tumor. We had the patient moved to the infirmary; she had vomiting, rapid pulse and high temperature; her abdomen was opened and we found an immense cyst on one side and, like the other case reported, a smaller cyst on the opposite side. The large cyst was of a dark-bluish slate color; there were a great many adhesions and new adhesions were forming. Peritonitis was active around it. After tapping the larger cyst to get it out, we found that the pedicle was twice twisted, the circulation being shut off from the sac; it was sloughing, and peritonitis active. The interior of the tumor was filled with clots and dark colored fluid the result of hemorrhages in the interior from obstruction of the circulation by this twisted pedicle. We removed both tumors, the cavity was thoroughly irrigated and drained, and she made one of the most prompt recoveries that I have ever known. There was not an untoward symptom of any kind.

These two cases are very interesting as confirmatory evidence of the especial fact that ovariotomy is the most successful major operation known to surgery. I believe that much of this is due to the fact that ovariotomy is largely in the hands of a few surgeons, and that the statistics of ovariotomy are furnished mostly by surgeons who have had large experience and have acquired results which can only be attained by careful attention to all details of the operation.

I will mention another ovariotomy: A young lady twenty-one years of age, unmarried, was brought to me from Daviess County, Kentucky, the latter part of October, with ovarian tumor. Diagnosis was clear. She was very ill when she arrived, and when I took her temperature it was 103.5° F., with a rapid pulse. That night she had persistent vomiting, which on the following day became of that character which belongs to peritonitis—green serous vomiting. On the second day I found her in such a serious condition, evidently from peritonitis—high fever, very rapid pulse and vomiting—that I decided to operate at once. I found a very large ovarian tumor extending up to the diaphragm, a multilocular cyst, with double twisted pedicle and with a sloughing sac. In separating the adhesions with my finger the sac ruptured and the pus contained in the tumor ran out over the table. I should judge that at least a gallon of pus ran out of the tumor. As is usual in these cases, there was a smaller cyst on the other side. The cavity was thoroughly irrigated with about three gallons of water and the patient put to bed with very considerable shock. She reacted very well and the pulse came down to 120 in six hours after operation.

The next morning the nurse telephoned me that the patient was bleeding at the nose. I thought this was merely an accidental circumstance. When I took the temperature the next morning it was 101.5° F., pulse still rapid, over 120. She had a red spot on either cheek, and presented a very unfavorable appearance. During the day delirium occurred and that evening her nose bled again. The next morning examination of the body disclosed rose-colored spots, diarrhœa had come on, and I found that I had done an ovariotomy in the midst of an attack of typhoid fever. She went on through this attack, but so far as the ovariotomy was concerned the result could not have been better had she been in a perfectly afebrile condition. She was five weeks in the infirmary with typhoid fever of a characteristic type. It was a very severe attack and

the temperature went up afterward to 104.6° F. She has now fully regained her health.

I merely mention this to illustrate another complication of ovariotomy and to still further confirm Mr. Greig Smith's statement that it is the "most successful major operation in surgery."

STRICTURE OF THE RECTUM.*

J. M. MATTHEWS, M. D.

About eight months ago I was called to see a lady thirty-two or thirty-three years of age, a widow, who, upon examination, revealed an excessive infiltration and stricture of the rectum extending, I should say, for six inches up the gut. At that time I knew nothing about the history of the woman. The evidence to my finger inclined me to the belief that it was syphilitic, though, taking her station into consideration, I would have doubted it if I had not seen many cases in women where virtue was not to be questioned. So I avoided giving a positive opinion as to the nature of this infiltration. I ascertained that she had had trouble with her husband and left him, and a relative told me that the man during his married life had syphilis, which is confirming evidence that my opinion was correct.

Now, as there is a pathological question which arises here, I want to state or rather reiterate, my opinion about the etiology of stricture of the rectum; that is, that the vast majority of strictures is produced by syphilis, and if I see a stricture of this portion of the gut that is not syphilitic, I strongly incline to the belief that it is cancerous. And vice versa, if I see a case that is suspected to be cancerous and it turns out not to be cancer, I am on record as saying, and still say, that I believe it to be syphilitic in the majority of patients. I do not want to be understood as saying that I believe all strictures of the gut that are not cancerous are syphilitic—I am misquoted in that particular and have tried to correct the matter in the Societies, etc., but there are some who will not hear it. My position then is this, and the case in question is one that will bear me out, that if the evidence, clinical history, etc., goes to prove that a stricture of the gut is not cancerous, then it is generally syphilitic.

*Reported to the Clinical Society of Louisville, Jan. 10, 1893.

Now this woman was, or had been, married; was then a widow; I knew nothing of her clinical history, nothing of her married life or surroundings, and I believed that she was suffering from syphilitic stricture. Naturally it would be asked why I supposed so. Upon this point I wish to say that there is evidenced to the finger a peculiar condition of affairs that attends syphilis or syphilitic infiltration of the gut, that does not obtain in any other character of affection that would produce, by its pathological changes, a stricture. I found in this woman's rectum a fibrous, non-yielding, hard stricture or infiltration—I do not know that the word hard should be used, because it so closely simulates the nodule that is sometimes felt in cancer. When the finger is introduced into the rectum, so far as it is inserted this stricture or infiltration does not give way, does not bleed; there is no especial odor or anything of that nature. This in contra-distinction to the cancerous infiltration which, usually at least, does give way to force, often has that peculiar odor of cancer, together with the other histological evidences that are brought about, or exist in such cases.

This woman had that condition. The patient was put under chloroform and I broke this stricture. I know my position in that one particular has been criticised. Men who are authorities in rectal surgery say that it is a dangerous procedure to break a stricture of the rectum. The majority of those who write upon the subject claim that gradual dilatation is the best method. I am so thoroughly persuaded that this position cannot be maintained that I never practice gradual dilatation of any stricture of the gut, be it benign or syphilitic—and I make the distinction between benign, syphilitic and cancerous stricture of the gut. They claim that breaking the stricture is dan-

gerous because it produces great shock. I have only seen one single instance where great shock attended it. They claim that you may tear the gut, as my good friend Bauer, of St. Louis, says, into tatters. I claim that by breaking the stricture we accomplish more in one minute than we could in one year by dilatation. This lady went on and it is needless to say she improved, because she had suffered before this operation with obstinate constipation. She could not have a free evacuation of any reasonable amount at all when I operated upon her. After that she had full, free evacuations for a number of months. Consequently her general health improved. After a lapse of some time I was summoned to this woman again, and I found, what I find in all cases of syphilis of the rectum, a re-constriction. I maintain that stricture from syphilitic causes is just as incurable as cancer. I do not think one was ever cured in the world. I do not believe that iodide of potassium can cause the absorption of a syphilitic stricture. I proposed to the family of this woman to do a different operation. I submitted the possible necessity of a colotomy assuring them that she could never get any better, at least could not recover, by breaking the stricture; I saw in the case, if it be syphilis, great advantage in a colotomy. They told me to submit it to the patient—she was a very sensible business woman—I submitted the proposition, and she gladly accepted it and appointed a day for me to do the operation upon her.

In the interim, on re-examination, I found in addition to this close constriction, a deposition of material extending likely into the sigmoid flexure, and at that sitting I also examined her uterus and, to my surprise, I found the womb in such condition as to persuade me that it was cancer.

Now a question arose in my mind, and it is the main question that I wish to smbmit to the Society: Was I wrong in my first conclusion? If this woman had a cancer of the uterus is it not simply an extension from the rectum? Or, as I am more inclined to believe, and it is a pathological question that I have never been able to settle in my own mind, is it not true that she may suffer from this syphilitic deposit in the rectum and that it has undergone a cancerous degeneration? I was not willing, therefore, to rest the case upon my own opinion and asked her to see a gynecologist. Dr. L. S. McMurtry kindly examined her and informed me that there was excessive cancerous disease of the uterus; and I said to him at the time if that was true I did not believe colotomy was advisable. I will not occupy time giving my reasons why colotomy was not justifiable, nor the advantages of performing a colotomy in that condition. I was compelled to say to this good woman that I did not believe even the *dernier-ressort* of colotomy would benefit her at all. She is a good Christian woman, accepted the burden and is prepared to die.

This is the condition of the patient today, and the main point I wish to raise is, do these syphilitic deposits, or does syphilis, degenerate into cancer or malignancy? I believe that I was correct. I am persuaded that it was syphilis of the rectum in the beginning. She gave a syphilitic history, after I ascertained from other quarters that her husband had syphilis. The evidence is clear and positive that it was a case of syphilitic stricture of the gut, and yet I find cancer of the womb. It is a strange coincidence if the woman is suffering from cancer of the uterus and at the same time syphilitic deposit of the rectum.

Bugs and Bug Poisons.

Ever since Koch, some ten years ago, promulgated his famous dicta about the germicides, the majority of doctors have concurred in the belief that the bichloride of mercury is the disinfectant *ne plus ultra* and *sine qua non*. Another eminent bacteriologist, however, now bobs up and asserts that the bichloride of mercury is no good on bugs whatever, or words to that effect. Thus do the old faiths change, but come what may, we shall cling to $HgCl_2$, for does it not salivate the bugs, and if it salivates them then can they no longer procreate, and if they cannot procreate, why, of course, their name is Dennis Bacillus.—*Denver Med. Times*

"Papa," said Wallis, "I wish you'd tell me a story."

"Very well, Wallis. What shall it be about?"

"About four hours long," said Wallis.

SOCIETY REPORTS.

THE SURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting Jan. 9th, 1893.

The President, Dr. A. M. Cartledge, in the Chair.

DISCUSSION ON APPENDICITIS WITH REPORTS OF CASES.

Dr. A. M. Vance: This gentleman is forty-two years of age; some time in September last he was taken with constipation; he was attended by Dr. H. M. Goodman; about the tenth day after the attack I was called in consultation. During the first ten days of his illness there had been considerable pain referable particularly to the appendicular region, but when I saw him there was no severe pain, not much tenderness, not much tumor. However there was some swelling in the ileo-cæcal space, evidence of pain on deep pressure, and some tumefaction, Forty-eight hours afterward I opened a large abscess in the right loin, making an incision about the middle of the ileo-costal space, the man was then in delirium, it being almost impossible to hold him in bed. Quite a quantity of very offensive pus was evacuated together with considerable fecal matter, also this appendix vermiformis, which had separated spontaneously, and a number of enteroliths which were not preserved. These enteroliths were very hard, about the size of a lead pencil, and two inches in length. Evidently when Dr. Goodman first saw this case there was a circumscribed abscess around the appendix, which afterward ruptured into the post-peritoneal space. The patient made an uninterrupted recovery and is here this evening to show the result of the operation.

This case illustrates a point which has been often questioned, viz: that the appendix does sometimes slough off into the post peritoneal space. After the operation and before the wound closed, a good deal of material came away looking like coffee grounds, and also a piece of egg shell about half the size of your finger nail. The quantity of pus removed was about 1½ quarts.

No. 2.—This patient is a man whom you all know, and who had a history, prior to my seeing him, of two attacks of what was supposed to be appendicitis. Dr. John Barbour was the attending physician in each attack. I saw him first early in the summer just as he was getting over an attack which passed away after the usual medicinal treatment. I saw him again early in October in a second attack and at that time, the family having repeated the medication used in the former attack, he was convalescent. I told him if he had another attack to advise me and I would operate upon him. I was called suddenly about a week after this, the message being that this patient had fallen on the street near the *Courier Journal* building, was in great pain and unable to walk. I sent my assistant, Dr. Rice, immediately to the scene. He found the man suffering with severe pain on the right iliac fossa and apparently unable to move. He gave him ½ grain of morphine hypodermically, telephoned for a conveyance and had the patient taken to his home. I went out at once and when I arrived found the man in convulsions, with pain paroxysmal in character, and being held in bed by Dr. Rice and two or three other men. We administered chloroform and made the ordinary incision over the appendix. It was with considerable difficulty that we located the appendix, it being very far back and high up, and when first discovered I thought it was very large.

Upon further examination it was found that the appendix was enveloped in a coil of omentum or fat which accounted for its apparent increased size. The appendix was about the size of a lead pencil and seemed to have nothing in it, particularly from the appearance outside. I excised it, however, and you will see here the remains of it. I have on the slide of the macroscope a section, the diseased condition of which can be easily determined by microscopical examination. After dressing the case I opened the lower part of the appendix and ten to twenty drops of muco-purulent material came out. No

drainage was used in this case; the man has recovered and has had no further trouble. Operation done October 4th.

No. 3.—Here is a little boy I saw I think in August. He had then been sick five weeks, and had been losing ground all the time, with evidence of a large abscess in the right iliac fossa. Dr. Hays had attended him and, upon leaving the city for a brief period, directed that a surgeon be called. I believed from the history of the case that it was the result of an appendicular abscess; took the patient to the Childrens' Hospital and opened it, evacuating a large amount of pus from the post peritoneal space. The thigh was flexed almost at right angles and could not be extended, but came down gradually after the abscess had subsided. He has now become perfectly well. In the operation I did not look for the appendix as it was post-peritoneal. The peritoneal cavity was walled off in this case.

I have three other appendices, with sections on the slide of the microscope, which I would like to have you examine. The first is a normal one. Second is an appendix removed from a patient of Dr. McDermott's. The history was that the patient was perfectly well on Sunday at dinner; Sunday night he was taken sick with abdominal pains; all day Monday he vomited and continued sick with abdominal symptoms; Tuesday he had very high fever, abdomen tympanitic. On Wednesday night at eight o'clock I was called and told him I thought he had a case of appendicitis; that perforation had taken place as the man had general peritonitis, and advised early operation. This was consented to after several hours delay. I made the ordinary incision and turned out a gangrenous appendix which had ruptured; the abdominal cavity being filled with pus and fecal matter. The cavity was thoroughly irrigated and the patient put to bed with considerable shock. He seemed to rally, however, the next morning he appeared to be doing well, but after that time he sank and died of septic infection in twenty hours. I believe if this patient had been operated upon sooner he would have been saved; showing the importance of formulating some rules in order to determine just when operative procedure is called for. Here is another specimen removed on Sept. 16th., Dr. Dugan assisting. The appendix had just gotten to the softening point, evidently would have perforated in a few hours more. There was a hood of omentum formed over it, making a perfect covering. This man had been sick only twenty-four hours. Has made a perfect recovery.

DISCUSSION.

Dr. W. O. Roberts: The first case reported by Dr. Vance is exceedingly interesting. There was considerable material, not only pus, but fecal matter in the cavity of the abscess. After evacuation the fecal matter ceased to escape entirely. We meet with cases of this character sometimes in which fecal matter escapes for a time after operation, then stops; in this case it seems to have ceased at once. It is a little unusual with sloughing of the appendix to get such prompt union as to prevent the escape of fecal matter.

The second case is also interesting. It seems that every attack the patient had came on very suddenly. The narrator did not state how long they lasted. I saw the appendix soon after it was removed, and as Dr. Vance says, there was a good deal of fat about it. The only evidence of trouble that we could detect at the time, was that the appendix seemed to be thickened. The doctor says under the microscope, however, it shows unmistakable evidences of inflammation. The man has now gone longer than he did before operation without a similar attack, and I hope he will be permanently relieved.

Dr. H. H. Grant: There is one point I would call attention to. Dr. Vance reports two cases in which the abscesses were found outside the peritoneal cavity, though the focus in each instance was clearly within the cavity. These illustrations strengthen the position of later pathologists that these abscesses always have an intra-peritoneal origin, no matter where the products of the inflammation are found. The question of the pathology of these deposits is the key to the treatment, hence every light on the subject is to be made use of in the appropriate application. The subject of appendicitis is too much contested to admit of settlement in these discussions, and though it were easy to talk at length of it, it is unlikely we can arrive at any definite conclusion.

Dr. W. C. Dugan: The subject of appendicitis, of course, is one of great interest to all. The first case reported by Dr.

Vance is one of especial interest to me, and I have come to the conclusion now that most all of these cases die from suppurative peritonitis. Very often gray patches are observed over the cæcum, colon and intestines, and I believe that these cases are almost uniformly fatal. I remember two cases I have operated upon presenting this condition, where the patients seemed to bear the operation very well, but afterward died of septic paresis —seeming to have paralysis of the vaso motor system.

The second case is also very interesting, showing so little evidence of disease and yet the symptoms were very much aggravated. I remember a case I recently sent to the Norton Infirmary from the city hospital. A patient who had been treated in Chicago, then stopped here on the way south and had several attacks of abdominal trouble, closely following each other, at the city hospital. At the Norton Infirmary I opened the abdomen and, as expected, found the appendix filled with pus, but, to my very great surprise the cavity was found to be entirely free from any inflammatory process—it was simply a cold abscess. The patient was very promptly relieved by the operation, and left the Infirmary in a short time.

Dr. L. S. McMurtry: The subject of appendicitis has received a great deal of attention in medical journals and society discussions during the past two years. It is natural that it should, both on account of the vital importance of the subject and the fact that our knowledge of the disease, its complications and severe mortality, and its successful treatment are the work of American surgeons. Ovariotomy and the foundation of abdominal surgery laid thereby, together with appendicitis and its operative treatment, are among America's great contributions to surgery. While appendicitis has been so freely discussed and written about of late, there is much yet to learn of the disease, and the rules guiding operative interference are by no means clearly established. Appendicitis is the most common cause of peritonitis in the male and, if we study the mortality reports of any of our cities, we will realize how common is the disease by the frequently recorded lists of males dying of peritonitis.

I do not know how I can contribute anything to the interesting discussion of the evening better than by exhibiting a specimen and reporting some cases illustrating the several phases of appendicitis.

No. 1.—Here is a vermiform appendix which I removed by abdominal section one week ago yesterday. It is the largest appendix I have ever seen; it is as large as a section of the distended ileum; thickened by inflammatory exudate. It ruptured at this point. At least three ounces of foul pus were poured into the peritoneum. The case from which this appendix was removed, has a history which I would ask you to contrast with that of another case which I will relate further on.

The patient is a woman, aged thirty-four years. She has been ill more than a year; being confined to her bed for days, and then up and about for a time. For several weeks prior to her removal to this city last Saturday week, she was confined to bed with acute peritonitis; she had a temperature of 104° F.; pulse 130; sweating copiously, and a distended abdomen. I opened the abdomen in the right semilunar line and evacuated a quart of foul pus and, after separating adhesions, removed this large appendix, irrigated with two gallons of hot water, and packed the iliac fossa with iodoform gauze. She reacted well; the pulse and temperature came down promptly, and she is now convalescing smoothly.

No. 2.—Now compare the case I have just mentioned with one that I saw in Georgetown, Ky., last Monday, in consultation. A gentleman fifty-four years of age, who occupied a very distinguished position in the educational affairs of Kentucky. He suffered with la grippe and had been in bad health for two years. He traveled in Europe last year for his health. He was taken sick one week ago last Friday; his physician was called, and the patient seemed to be suffering from an attack of colic. The next day he had a little pain and complained of a symptom that I have seen in a number of cases of appendicitis, very severe pain in the head of the penis and retraction of the testicles. He went along in this way until Friday evening when he was taken worse, still suffering from the pain in the bowels and constipation; he had a temperature of 100° to 100.5° F.; the pulse never went above 100. His physician, Dr. J. A. Lewis, recognized the serious character of

the disease. I saw him first on Tuesday of last week; the bowels had moved in response to an enema; there was no tumor in the right iliac fossa; there was a little resistance of the abdominal muscles on that side, but they were not rigid. He had a pulse of 88. I saw him again the next morning and he seemed somewhat better; bowels had moved, he had taken some nourishment; pulse 82, abdomen softer; no tympany, no tumor, and the fever seemed to be subsiding. That morning I took the train and came home. At nine o'clock that night I received a telegram to come immediately as the patient was very much worse. An hour afterward I received a second message not to come, the patient was dead. A post mortem was made and perforative appendicitis with abscess was the cause of death.

Contrast this history with that of the first case reported by me, where the woman had been sick a year, and where the appendix had undergone all of these pathological changes which we see are very extensive.

Of course the most important feature in connection with this subject is, when should operative interference be resorted to. Prevailing professional and public sentiment will not support a surgeon in operating in a case like that of the gentleman at Georgetown. There is little risk connected with the operation in skilled hands, and I believe, if we had opened this man's abdomen, we might have saved him, although his general condition was very unfavorable for resisting any disease or repairing any injury. I would invite attention especially to the fact that there was no tumor, very slight elevation of temperature, pulse under 100; nothing to indicate perforation and abscess save pain, retraction of testicle and pinched features. The diagnosis of appendicitis was made positively, and this case adds to the facts already recorded, that an operation should be done when a diagnosis of appendicitis is established. The risk of waiting for symptoms is far greater than that of the operation.

Dr. W. H. Wathen: I will allude briefly to one or more of the cases that have been reported, and give my experience in connection with cases of this character. It is difficult to decide in many of these cases when to operate, because of our inability to make a correct diagnosis. Persons who are engaged in this kind of surgery, or in abdominal or pelvic work are constantly reminded that when the abdomen is opened they find a condition that they had not expected, and that which they had expected is often entirely absent. I have seen a number of cases, where the subjective and objective symptoms indicated appendicitis better developed than in most of the cases upon whom laparatomies have been performed, who recovered permanently without operation; or in which the diagnosis was not correct. Some of these patients had a temperature from 101° to 104° F., obstructed bowels, rapid pulse and a well-marked tumor the size of a large orange in the location of the appendix. I saw one of these cases before any operations for appendicitis had been performed. She made an uninterrupted recovery and now, twelve years afterward, is perfectly well and has had no symptom of a recurrence. Another case: a banker in this city, three years ago had a tumor larger than a goose's egg in the appendicular region, with pulse 120, temperature 103° F., and all the symptoms of appendicitis. He was not operated on. In seventy-two hours the tumor had disappeared and his temperature and pulse were normal, and within less than a week he made a trip to Knoxville without inconvenience. He has had no symptom of a recurrence of the disease. I operated upon a patient last summer, who had had three attacks of what was diagnosticated by excellent physicians appendicitis, and upon one or more occasions the several doctors in attendance decided that she could not recover; she vomited fecal matter; however she did recover from these attacks, and in the operation the appendix was found to be perfectly healthy. But there were extensive peritoneal adhesions binding large coils of the intestines together, probably caused from an injury she received three years before when thrown from a buggy. I could report a great many instances of mistaken diagnosis where the symptoms were just as marked as it is possible for them to be.

While appendicitis is usually intra-peritoneal it is sometimes extra-peritoneal, as in the case reported by Dr. Vance. These are rare cases, but they do occur. Extra-peritoneal abscess in the right inguinal region with no involvement of the appen-

dix is sometimes reported as appendicitis. These abscesses do not always point in the same direction. I have seen several cases where the abscess pointed toward the buttock, and in one case, when it was opened, I could introduce my finger deep in the pelvis between the bone and Poupart's ligament. This abscess contained nearly a gallon of pus. I am sure the appendix was not involved. About the only positive evidence that the appendix is involved is the fecal matter in the abscess. Recently I treated a case of this kind where the pulse was 140, and the temperature 105° F., with a well-marked tumor; all the symptoms having existed for ten days. I made the usual incision and removed a pint of pus in which there was a fecal concretion the size of the end of my little finger, showing that the trouble was the appendix. Had there been no fecal matter in this case no one could have said positively that it was appendicular in its origin. This case, like one reported by Dr. Vance, had no further fecal matter in the cavity. It was packed with iodoform gauze and the patient made an uninterrupted recovery, having no elevation of temperature the morning after the operation.

In the case reported by Dr. Vance—in which the gentleman was attacked very suddenly and fell—I am inclined to the opinion that it was not appendicitis, for, if the appendix is not normal, it is so little diseased that it could not have caused such symptoms as were manifested, particularly the suddenness of the attack. I believe there will be similar attacks in this case.

Referring to the Georgetown case it is probable that the trouble was appendicular, but that could not be proven without a post mortem examination. For as I have remarked the subjective and objective history of these cases very often will not enable us to come to a conclusion that is always correct.

Dr. A. M. Vance: To what other cause would you attribute the acute peritonitis with the tenderness, tumor, etc., in the right iliac fossa of the male, except the appendix?

Dr. W. H. Wathen: It might have been caused by a pelvic or abdominal abscess with no involvement of the appendix, psoas abscess, renal or peri-renal abscess, abscess of the liver or gall bladder, etc. It is one of the difficulties that we have to labor under in these cases to determine exactly what the nature of the trouble is. As a result we operate where the operation is not indicated and, again, refuse to operate upon cases that require surgical interference.

Dr. C. W. Kelly: As regards the relation of the peritoneum to the cæcum and appendix vermiformis. Very frequently it is found that the peritoneum embraces only one half of the cæcum as it extends around the appendix; occasionally it entirely surrounds the cæcum and the appendix vermiformis, occasionally it goes entirely over the cæcum so that it may be either an intra- or extra-peritoneal structure. The appendix has a small mesentery of its own, which may not entirely close behind.

In regard to operative procedure for appendix I want it understood that I am an advocate of surgical interference in these cases when it becomes necessary, but the most important point is to determine just when it is a necessity.

Dr. W. C. Dugan: I would like to call attention to another symptom which is sometimes present in appendicitis, and that is cystitis. I have seen several cases having this symptom. I think there is no mention in the text-books up to 1884, of involvement of the penis or bladder in appendicitis.

Dr. A. M. Cartledge: I was very much interested in the cases reported by Dr. Vance, and am not inclined to say that we are discussing appendicitis too much. I fully agree with Dr. McMurtry that a classification should be made of these cases by which we can have some rational means of determining cases demanding operative interference, and the time at which the operation should be done. As surgeons, I think we are all indebted to Professor Kelly for the correct position he has taken; we are also indebted to Treves for his valuable work upon this subject. Read any medical journal and we find almost as many opinions expressed as there are writers in regard to the operation for appendicitis, whether the abscess is intra- or extra-peritoneal, etc. In regard to Dr. Wathen's remarks, I think it has been fully demonstrated that the appendix may be the offending organ, whether the abscess is intra- or extra-peritoneal, and that in either

case we may have fecal matter in the abscess. The appendix is usually found to have a mesentery, but frequently it is held in place simply by a band of connective tissue posteriorly, and it may rupture either posteriorly or anteriorly through the peritoneal covering, and you can have a fecal abscess either intra- or extra-peritoneal.

Concerning the case reported by Dr. McMurtry, in which he says the trouble was appendicular in origin and that large quantities of pus was evacuated. In most cases, especially those that recover, we have a circumscribed peritonitis and the abdomen proper is not opened. I believe that where you have rupture before protecting adhesions or walls are formed, in ninety cases out of a hundred, though operation is performed and the cavity washed out, the patients will die from septic infection. I believe every case characterized by acute pain, like the case reported by Dr. Vance, where a man fell on the street, is going to be followed by rupture of the appendix and early operation is imperatively demanded. I believe that pain is our chief guide in these cases, and of more importance than elevation of temperature or tumor. I saw a case recently with Dr. Chenoweth, where a man had several recurrent attacks of appendicitis from which he apparently recovered. He came to the city one morning and was taken suddenly with severe pain in the abdomen, having many symptoms of colic. From the previous history of the case we diagnosticated appendicitis, and he was operated upon a few hours afterward at the Infirmary. The appendix was removed and was found to be greatly distended, and popped upon being severed. I believe that this appendix would have ruptured from the great distension in less than six hours.

In regard to what Dr. Wathen says about the diagnosis being obscure. This is simply a greater demand for the expert physician. As before stated, I believe that, where there is severe pain, with or without rise in temperature, and tumor, these cases shall be operated upon and, if the appendix is found diseased, remove it whether diagnosis of appendicitis has been made or not.

Dr. W. H. Wathen: I did not say that the presence of fecal matter in the pus was an indication of intra-peritoneal abscess. I reported a case of extra-peritoneal abscess where there was a fecal concretion in the pus. I said that fecal concretions or fecal matter in an extra-peritoneal abscess was an evidence that it was appendicular in origin.

Dr. A. M. Vance: I am thoroughly convinced that one of the most important things in a case of appendicitis is to know when the doctor should step out and the surgeon come in. My experience has been that doctors, instead of calling in a surgeon at the beginning of an attack, depend largely upon the judgment of the patient as to when he should be called. This is a point that I think we should emphasize with the general practitioner—that the surgeon should be called to see the case early—since it is a necessity for the safety of the patient. I agree fully with what Dr. Cartledge has said and think he has covered the ground very thoroughly. I believe that the safest plan would be to operate on all of these cases. An argument in favor of operation is that most cases of appendicitis recur. I have a case under observation now which ought to be operated upon; the man has a well defined tumor as big as a duck's egg; he has had fever and severe pain; has been under opium, but his bowels have moved. I am sure that if this patient recovers from this attack he will have another. When I first saw him I advised operation which was declined, and I have not seen him since. I saw a patient the other day with Dr. Tuley, very much like the case reported by Dr. McMurtry which he saw at Georgetown. The history of the case was such that it made the diagnosis more difficult. Patient was a boy nineteen years of age; a carriage trimmer; he was in the habit of carrying tacks in his mouth, occasionally swallowing one. Dr. Tuley saw him twenty-four hours after the first appearance of pain, which was referable to the right iliac fossa, and advised operation. I was called in consultation, found pain in the left side and the boy was considerably better. I thought possibly the trouble might be fecal impaction and advised a high enema. This was done, the bowels moved, fever passed off and he went on for five days seemingly convalescent. Then suddenly he went into collapse, evidently from perforation of the appendix or some other part of the gut, and died very quickly. I am sorry that I did not

do an exploratory operation in this case, but I did not feel that the severity of the symptoms warranted it. It afterward developed that this patient had swallowed tacks a few days before he was taken ill. No post mortem was held, so it will never be proven whether or not the tacks had anything to do with the trouble.

Dr. C. W. Kelly: I have seen a great many cases of appendicitis and have never had a death result.

Dr. L. S. McMurtry: Many cases of appendicitis ending in death are diagnosed as idiopathic peritonitis, and so reported. The mortality from recurrent attacks of appendicitis is very severe.

Dr. C. W. Kelly: I do not want to be understood to even indicate that I do not favor operation for appendicitis, because I do favor it. I only claim that while a man's experience as far as it goes may be good, yet it must not be convincing. You may have five cases of appendicitis, and four of them would require operation; again you might have ten cases and not one of them require operative interference. The operation can be performed almost without danger, and I believe in giving the patient the benefit of the doubt. I believe that many people might be saved by an early operation in cases where appendicitis was not made out.

THE CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting, January 10th, 1893.

The Vice President, Dr. J. M. Krim, in the chair.

Dr. J. M. Mathews reported a case of "Stricture of the Rectum." (See page 290.)

DISCUSSION.

Dr. J. G. Cecil: It is an exceedingly interesting case, and I can hardly let it go by without asking at least a question. I would like to know of the narrator what was the probable age of the cancer in the uterus at the time it was discovered, and how would that length of time, that probable age of it, compare with the first examination or first evidence of stricture of the gut? To my mind I do not see any special reason why this woman could not have had a syphilitic stricture of the rectum, and at the same time cancer of the womb; so that Dr. Mathews might have been entirely correct in his original diagnosis and equally correct in the conclusion which he came to, that there is nothing perhaps in a surgical way that gives any hope. The slight experience I have had with syphilitic stricture of the rectum bears out what Dr. Mathews has said as far as gradual dilatation of the gut is concerned where syphilitic deposits occur, that it does not amount to anything, at least I have never succeeded in even relieving the patient to any great extent. It is a constant source of trouble both to the physician and the patient; dilatation, in the very crude way in which I have been able to perform it with the ordinary instruments, has been very unsatisfactory, so that if rapid dilatation can be done as Dr. Mathews says, without danger, it seems to me that it would be infinitely preferable, as by rapid dilatation under anæsthesia we can accomplish at one sitting results which would require, perhaps, six months or a year to obtain by gradual dilatation.

In regard to syphilitic stricture of the rectum—I am not very familiar with the literature of the subject, but it seems to me that some of them situated low might be resected, especially in the female, as you would have the vagina through which to work if necessary, or at least to help in getting at the case. I would like to ask Dr. Mathews if this would not be the proper procedure.

Dr. L. S. McMurtry: I am convinced that Dr. Mathews' views upon the case reported are correct. I believe the stricture is syphilitic, and that the development of carcinoma of the uterus was subsequent as to the deposit about the rectum. Cancer of the uterus varies as to the degree of malignancy and rapidity of progress. In the case under consideration the process of cell proliferation and infiltration has been rapid in its progress. I am

sure that in this case the syphilitic ulceration antedates the cancerous development in the cervix uteri.

Dr. J. M. Mathews: While Dr. McMurtry was speaking I was reminded of the fact that upon several occasions lately this patient said to me, "Doctor, I am losing a great deal of blood," describing it as "gushing from her." For the first time or two I, of course, regarded it as dependent upon the rectal trouble, and thought it strange that she should lose this amount of blood from a syphilitic deposit, but when she came to explain that the hemorrhage was from the uterus, I was led to make an examination of it. Now you will notice here is just as extensive or, perhaps, more extensive infiltration or pathological change in the rectum without the least loss of blood, the hemorrhage being only from the cervix uteri. This is the main point I make in drawing the distinction between syphilitic deposit and malignant deposit. Here she has had for several years a syphilitic deposit in the rectum with no discharge of blood, and within a little time after the development of the trouble in the uterus, she loses a great deal of blood, which is a point I think in making my diagnosis stand.

In regard to Dr. Cecil's remarks: When this patient first came under my observation I examined her uterus as best I could with my finger and there was no evidence of any trouble, nor did she complain of any until she was losing blood, and only called attention to that within the last few months. Therefore the rectal trouble must have antedated the cancerous condition of the uterus a number of months, if not several years, from the fact that when I first made an examination of the rectum, the constriction was so small that I could not pass my little finger through it. The treatment of strictures of the gut by excision has been in vogue for a number of years, and it is more popular now than it has ever been, because some American authorities especially, are in the habit of resecting or exsecting strictures of the gut where they are within reach, and where healthy mucous membrane can be secured above and pulled down and stitched to the true skin. Of course this can only be done in exceptional cases where the stricture occurs sufficiently low to enable you to get at it. If it is five or six inches up the gut, it is impossible to reach it to resect. Another thing that should be taken into consideration in this connection, and that is in resecting we interfere with the sphincter muscle, which is not done in dilatation for stricture. I believe dilatation preferable because we not infrequently see incontinence of feces following resection for stricture.

The following from the *Hospital Gazette* is *good*. Having an important engagement two or three weeks ago, I was unable to attend the general meeting of one of the medical societies, and asked a friend to send me a few notes of the meeting. The following came to hand:

ROYAL PIMPLE-CURING SOCIETY.

Dr. Makem-Pay, President, in the Chair.

Dr. Cutemout related the case of a patient who had for some years past suffered from a very painful and interesting complaint. Not having the notes of the case before him he was compelled to speak from memory, and, unfortunately, the symptoms had long since been forgotten. The etiology of the disease was very obscure and he proposed to deal with this more fully on a subsequent occasion. As to treatment, he had found it necessary to employ a great number of remedies, and when last seen the patient reported himself as improving—he was unable to say under which particular treatment. He had since lost sight of the patient and could not, therefore, say whether the improvement had been maintained. *Dr. Swindem* expressed the great interest he took in the case so clearly brought up before the Society, and asked for further details, particularly as to whether the bowels were regular. *Dr. MacAdamized* said he had met with a similar case in his private practice, in the person of a wealthy American gentleman who, after having been treated by all the leading specialists of Europe and America, recovered in the course of three days in his private hospital at 24 Pignomy Street, W. *M. Herringfry* proposed a vote of thanks to the author of this interesting paper.

(Left under discussion.)

Macaroni makes not a bad catheter when there is nothing else at hand and Nature is urgent. Dr. R. C. Kirkpatrick, of Montreal, tried it one day with success.

CORRESPONDENCE.

NEW YORK LETTER.*

Last Saturday night a dinner was given at one of the most fashionable hotels of the city in honor of Dr. Jenkins. More than four hundred guests assembled to pay their respects to the man who kept cholera out of New York. Prominent medical men were noticeably absent, while the leading warriors of the Tammany tribe had things their own way in eulogizing their popular medicine-man. Dr. Jenkins, who by this time is the well-established brother-in-law of Dick Croker, made a speech which showed that he was not only very well pleased with the existing condition of quarantine affairs in general, but that he was satisfied with himself in particular. Senator Hill, Francis K. Thurber, Mayor Gilroy, and several other noted men praised the worthy doctor, comparing him to Horatius and to other celebrities of historic and mythologic fame. These men, whose ideas of sanitation are in an inverse proportion to their propensities for political scheming, fail to make a very brilliant showing when compared to Drs. Janeway, Loomis, Jacobi and the other members of the committee which recently made a report to the Academy of Medicine, that was in no way flattering to the quarantine facilities of this port or of our quarantine officers. While these political leaders may be popular to-day, they will one day lay forgotten in their little urns, when the names of the physicians mentioned above will be shining light, in the firmament of the great men who have been.

★★★

New York City is the possessor of the finest operating theatre in the world. The building was completed about two months ago at an expense of a quarter of a million dollars which was bequeathed by Dr. Syms. It was planned under the direction of Prof. Chas. McBurney, who spent several months during the last Summer visiting the various hospitals of Europe, and studying their operating theatres. The building is in connection with Roosevelt Hospital. Externally it is of pressed brick and a small and unimposing looking building, and one would wonder how so large a sum could have been expended in its construction. But once inside, the observer wonders how such a sum could have furnished it so elegantly. The interior is of pure marble and consists of the amphitheatre, a room for anæsthetizing and a couple of small rooms for instruments and surgical dressings. There are three hundred seats so arranged that from any one of them the spectator can gain a perfect view of the pit.

Dr. McBurney holds a clinic in the Syms' Operating Theatre every Saturday afternoon; at the clinic the operator, the assistants, and the male and female nurses are dressed in a complete suit of white. With the popular Professor's fluent language and the beauty and richness of the surroundings, the clinic assumes more of the nature of an entertainment than of a place for surgical study.

★★★

Dr. Dudley, lecturer on gynecology at the Post Graduate, performed a Cæsarean section last week. The woman had a contracted pelvis which measured but two and a half inches in the congugate diameter. The child was within four days of full term. The patient had been pregnant once before, at which time craniotomy was performed; it was considered that as she knew her incapacity to bear a living child, and had a second time subjected herself to the dangers of pregnancy, that it was justifiable to give the child a chance, the previous one having been sacrificed for the mother. This Cæsarean section was chosen instead of craniotomy, although the higher mortality of the former was recognized. A seven pound child was delivered. At the present writing both mother and child are doing well. At no time since the operation has the mother's temperature been above 101° F.

★★★

A couple of months ago peroxide of hydrogen had quite a boom in the treatment of gonorrhœa. Several reports were made by various physicians of its

*Special Correspondent to The Medical and Surgical Reporter.

almost miraculous effects, particularly in virgin cases. It was used as an injection three times a day, undiluted ten volumes strength. It was claimed that the powerful antiseptic properties of the drug rendered it superior to the older remedies and that it possessed the virtue of being unirritating. The drug has received an extended trial in the out-door department of Bellevue Hospital and has been found wanting. It has no advantage over the older remedies, and in most of the cases seemed to have no beneficial effect in cutting short the progress of the disease. Certainly it does not abort it, as has been claimed, no matter how early in the disease it may be used. It seems that it requires a long time for some of the profession to become aware that gonorrhœa is not built on the abort plan.

ACNE.

Dr. A. F. Koontz in writing on this subject states that this name is derived from the Greek word *akun*, meaning *vigor*, affecting those in the vigor of life, during the active sexual life of both sexes.

It is an inflammatory affection of the sebaceous glands, selecting by preference those connected with the rudimentary hairs, and is usually located on the face, neck, back and occasionally the breast.

Acne is undoubtedly a reflex affection, dependent on the derangement and irritation of some of the internal organs, notably the sexual and digestive.

The lesions found are papules, pustules, tubercles and indurated nodules, and the disease is usually described under the names of Acne Vulgaris and Acute Indurata.

The Acne Vulgaris is most common in early life, and is a more acute form of the affection, the lesions being more discreet and running a more acute course, and is nearly always accompanied by a plentiful sprinkling of comedones.

The Acne Indurata is merely a chronic form of the preceding; the pustules, instead of maturing, being indolent, and assuming an indurated, nodular character.

In the treatment we must remember its reflex origin, and combine our internal and local remedies, being ever mindful of its chronic tendency and recurrence, until, in the majority of cases, it disappears with the full and *normal* establishment of the sexual functions.

To patients disfigured by Acne, though we cannot promise the traditional "Recamier" complexion, yet by a persistent and rational course we can give them a presentable skin, until time comes to their aid, and, more important than this, prevent the pitting and permanent loss of tissue which characterizes the chronic indurated form.

The only affections with which Acne is liable to be confounded are papular and pustular syphilides, and a papular Eczema; from the former it is differentiated by the history, and the more general diffusion; and in the papular Eczema the papules do not necessarily correspond to the sebaceous glands, and there is more infiltration of the intervening tissue.

The local treatment seeks to establish more acute inflammation and bring about a rapid maturation of the lesions.

This is usually done by some stimulating application, tinct. of green soap being most commonly used, washing the parts in very hot water.

All nodules and pustules should be freely punctured and the bleeding encouraged by the hot applications.

After the irritation has been kept up for a few days by the green soap, a mild stimulating lotion should be used, and sulphur washes particularly have given good results. The following is used by Dr. G. T. Elliott, of New York City.

℞ Zinci sulph.
Potass. sulphuret. } .....aa gr. v—xxx.
Aquæ rosæ..... ..... ʒi.
Sulphuris præcip..... gr. xx—xl
Sig: Apply to face three times a day.

This treatment should be persisted in until the face is cleared, and should be resumed immediately if the eruption shows any tendency to return.

With reference to the internal treatment, the sexual functions should be regulated, and any excitement of an unnatural kind—masturbation—should be strictly inquired into, as this is frequently the provoking cause in both sexes. The bowels should be regulated and the diet restricted to wholesome food, sugar being limited.

The indications being, according to Piffard, of New York, for arsenic, when there is an indolent papular element, and for the sulphide of calcium in those cases characterized by a plentiful crop of sensitive pustules.—*Hot Springs Med. Jour.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, FEBRUARY 25TH, 1893.

EDITORIAL.

A MODERN DON QUIXOTE CHARGING A WINDMILL.

"Fortune disposes our affairs better than we ourselves could have desired: look yonder, friend . . , where you may discover somewhat more than thirty monstrous giants, with whom I intend to fight, and take away all their lives; . . . for it is lawful war, and doing God good service, to take away so wicked a generation from off the face of the earth." "Consider, sir," answered Sancho, "that those which appear yonder are not giants, but windmills." "One may easily see," answered Don Quixote, "that you are not versed in the business of adventures; they *are* giants, and if you are afraid, get aside and pray, whilst I engage with them in a fierce and unequal combat."—*Cervantes.*

The *Journal of the American Medical Association* for February 4, 1893, contains an editorial on REMOVAL OF THE OVARIES AS A THERAPEUTIC MEASURE IN PUBLIC INSTITUTIONS FOR THE INSANE, which, as an example of correct reasoning from false premises, is to be admired though not imitated. We quote, (*italics are ours*):

1. "The State Board of Public Charities of Pennsylvania has recently been induced to take action upon the *sexual mutilation* of insane women, which has lately been introduced and practiced in one of the State institutions for the insane."

2. "The attention of the Board was directly called to this subject by its Committee on Lunacy which made a special report upon the subject of *Removal of the Ovaries as a Cure for Insanity.*"

3. It is intimated, by a quotation from the report of the Committee's secretary, that Dr. Joseph Price had already performed operations of this kind on four insane patients in the Norristown Hospital, and that fifty more had been marked down for operation by this method in the same institution.

4. The Editorial quotes the Committee as saying:

"As a general rule, to which there must be an occasional exception, we are forced to regard *experimental* operations upon insane women, for the purpose of restoring their reason, with disfavor, and to consider it unwarrantable and indefensible. As to the practice of such operations in our State hospitals, it is a matter of grave doubt whether a relative or guardian of an insane woman has the moral or legal right to give *consent* to the *unsexing* of the insane person. What redress would such a person have, if in *re-*

covering her reason she objected to her mutilated condition?"

5. "It is the opinion of Mr. Thomas Barlow, the legal member of the Committee, that in view of the *experimental* character of the work, it is brutal and inhuman and not excusable on any reasonable ground."

6. Dr. Morton is quoted as saying "that insanity is not a disease of the ovaries, nor of any other part of the body which is accessible to the surgeon's knife" and Mr. Barlow says "that legal consent of the patient for such mutilation can not be obtained."

THE REPORTER suggests for consideration:

1. It was not proposed to *mutilate* these women either sexually or otherwise. Each of them had been carefully observed and repeatedly examined by a learned and thoroughly qualified member of the profession of their own sex, and found with marked disease of the pelvic organs—disease such as ordinarily unsexes the patient long before the surgeon's interference.

2. It was not proposed by the physician-in-charge that the ovaries should be removed *as a cure for insanity*. They were to be removed for the *cure of pelvic disease* having its origin in the tubes and ovaries. By this means it was *hoped* to relieve suffering and bring about a state of physical health, thus putting the patient in a condition to be better treated for her mental disease.

3. Had Dr. Price been simply removing ovaries for the *cure of insanity*, why would only fifty have been marked down for the operation? Why not an hundred? or two hundred? The fact is only fifty were found with disease grave enough to justify a section, and *no operation* was intended for its effect upon the mind alone.

4. Does any one for a moment suppose that the operation of abdominal section for the positive relief of gross pelvic lesions is anything in the nature of an *experiment?* And if a guardian may not give consent for an operation of this kind, can he authorize the operation of trephining, or even the pulling of an aching tooth, or the removal of a diseased eye which is threatening total blindness by setting up a sympathetic inflammation in the sound eye? "What redress would such a person have if, in recovering her reason, she objected to her mutilated condition?"

5. Of course the opinion of Mr. Barlow, first, that the work is *experimental*, second, that is is "brutal and inhuman" ought to settle the question at once. A lawyer's opinion on medical and surgical questions is on a par with that of a doctor on legal matters. "Let the shoemaker stick to his last."

6. No one supposes for a moment that insanity is a disease of the ovaries and Dr. Morton said nothing new or startling when he gave utterance to the proposition quoted. Yet we do not suppose for a moment that he would deny the fact that insanity may follow and depend upon disease of the ovaries as well as other parts of the body.

The mistake made in the editorial referred to, and by all others who discuss this question from a like standpoint, is that they are fighting a figment of their own imagination. They first create a monster and then proceed most valiantly to destroy the object of their own creation.

They lift their hands in horror at "*mutilation,*" "*unsexing,*" "*experimental sections,*" "*removal of ovaries*" to *cure insanity,* while no one proposes to mutilate, unsex, experiment, or cure insanity *per se* by the removal of ovaries.

An insane person should be treated gynecologically just as any other person would be treated. An examination, diagnosis and treatment ought to be instituted independent of her mental condition.

Would Morton stop to consider the

question of insanity if a patient's leg was broken or she had a gangrenous foot?

Would Pepper refuse quinine in a case of malaria because of existing insanity? Would Parvin deny the forceps to an insane woman in a case of dystocia with an impacted head? If not, why should Price withhold the knife in a case of pus in the pelvis, or an ovarian tumor? Would not an abdominal surgeon operate for occlusion of the bowel ?

Such objectors are gems of consistency. They may trephine the skull, reduce dislocations, adjust fractures, give purgatives, diuretics or other depurative medicines, but the gynecologist must stay his hand even though pus absorbtion has gone on till the very brain-cells are saturated with toxic products, the effects of which are to destroy all normal function and give a disordered mind the result of a diseased body.

In conclusion we wish to remark that the removal of ovaries is not the only object, nor the universal result of an abdominal section.

TRANSLATIONS.

EXPERIMENTAL TYPHOID FEVER.†

According to Aviragnet (*Le Bull. Méd.*, Jan. 15, 1893), experimental typhoid fever is difficult to produce, because animals are naturally refractory to the typhoid bacillus. Consequently, in inoculating animals with the bacillus of Eberth, the object should be not to reproduce a faithful image of typhoid fever in man, but to determine a septicemia analogous to that produced in the same conditions by the coli-bacillus or by the microbe of cholera. This is not easy to do judging from the irregularity of the results obtained. The first experimenters who endeavored to produce an experimental typhoid fever by causing the animal to absorb the typhoid stools, most frequently obtained negative results. The researches which followed the discovery of the typhoid fever bacillus have given rise to results quite contradictory. Whilst Gaffky was unable to obtain anything, E. Frankel and Simmond, A. Frankel, Michael, Fodov, Seitz demonstrated the specific action of Eberth's bacillus. The results of their researches seemed to decide the question. Nevertheless, some time afterwards, Sirotisun, on one hand, Beumer and Peiper on the other hand, arrived at couclusions totally opposite; according to these authors the injection of cultures of Eberth's bacillus do not determine an infection, but a simple intoxication. Moreover, Beumer and Peiper thought that identical results should be obtained with inoffensive microbes, such as the *bacillus subtilis* and the bacillus prodigiosus, on the condition that large quantities be injected.

Chantemesse and Widal took up the question in 1887, and demonstrated that the typhoid bacillus, endowed with a certain virulence, determined in the animals a true infection. Cygnœus, Gasser, Gilbert and Girode confirmed these results. Two interesting works have been published in the *Annals of the Pasteur Institute* upon the action of Eberth's bacillus upon animals; one is by Chantemesse and Widal; the other by Sanarelli. The results obtained by these experimenters agree in every point; they are most interesting and deserve to be largely analyzed. They have caused a decided advance in the question of experimental typhoid fever.

The contradictions which the previous works offer reside in the fact that the researches have been undertaken most often without the virulence of the injected bacilli being determined. Chantemesse and Widal had already remarked, in their memoir of 1887, that the results could not be positive unless bacilli endowed with a certain virulence be employed. In their new work they follow up their idea and

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

increase and fix the virulence of Eberth's bacillus. Sanarelli has been guided by the same idea. This virulence once acquired, it has been easy to demonstrate that an injection of a pure culture of Eberth's bacillus was constantly fatal to the animals.

This is the method first employed by Chantemesse and Widal to increase the virulence of a slightly acting typhoid bacillus. A guinea pig is inoculated under the skin with a dose of four to six c.cm., of a typhoid culture, freshly taken from the human body; the animal habitually succumbs in twenty-four or forty-eight hours. The peritoneal cavity encloses an abundant serous exudate rich in typhoid bacilli. Two or three c. cm. of this fluid is taken, mixed with 10 c. cm. of bouillon and the whole left in an oven at 37° C., for some hours. At the end of this time a guinea pig is inoculated with four to five cc. of this culture (under the skin.) In this second animal the infection is already more rapid; this process is repeated from one guinea pig to another. The more the number of the passages is increased, the more may the inoculating dose be diminished. Two cm., then one, and finally $\frac{3}{4}$ of a cm., suffice to kill the animal in a few hours with proliferation of the bacilli in all the organs, and in particular in the blood, spleen, etc. The virus which suffices to kill the guinea pig by subcutaneous injection of $\frac{3}{4}$ cm., will also kill it in the dose of eight or ten drops when it is inoculated in the peritoneal cavity. Two cubic centimeters of the same culture injected into the peritoneum of a rabbit, or four cc. inoculated in its blood most frequently cause the death of the animal in twenty-four or thirty hours, with generalization of the bacilli in all the organs and in particular in the blood. But it is necessary to say that the virulence of a typhoid bacillus, even thus exalted, is inconstant for the rabbit.

Chantemesse and Widal have succeeded in killing guinea pigs with non-virulent or slightly virulent cultures, by injecting at the same time in the subcutaneous cellular tissue, or in the peritoneum of the these animals some cubic centimeters of a culture of streptococus sterilized for an hour by heating to 60° C. The animals succumb with generalization of the typhoid bacillus in the blood, the organs and the peritoneal cavity. On inoculating a second guinea pig with the culture provided by the first, the animal rapidly succumbed, although but a slight quantity of the sterilized culture of the streptococcus had been injected. On continuing the series of cultures the bacillus acquires a progressive virulence and determines sooner infection when the guinea pig has been prepared by the injection of the soluble substances of the streptococcus.

In these successive cultures the bacillus of Eberth always preserves the characteristics which are proper to it. Streptococci do not alone favor typhoid infection. Sanarelli has arrived at the same results with the *bacillus coli commune*. This is his method of proceeding: he inoculates five cc. of a typhoid culture of twenty four hours in bouillon, in the dorsal subcutaneous tissue of a guinea pig in the abdominal cavity of which, at the same time, are injected ten to twelve cc. of an old culture in sterilized bouillon of *B. coli*. The animal succumbed in the space of twelve to fourteen hours, and generally in the peritoneal exudate is found an abundant quantity of the bacillus of Eberth. A subcutaneous injection of five cc. of the culture taken from this first guinea pig, kills a second guinea pig when it has received, at the same time, not more than twelve, but usually seven to eight cc. of a sterilized culture of *B. coli*. Analogous results may be obtained with sterilized cultures of *proteus vulgaris*. The virulence of the typhoid bacillus may be more quickly intensified by the passage from peritoneum to peritoneum.

The action of soluble products afford an explanation why causes which enfeeble the individual (auto-intoxication or poisoning of external origin) may facilitate the invasion of the typhoid virus. The absorption of impure water which, in so marked a manner, determines the outbreak of typhoid fever, owes in great measure its infecting power to the cause noted above. The coli-bacillus plays, without doubt, a rôle in the etiology of typhoid fever, not only on the quality of the specific microbe, but as a more or less useful auxiliary, although inferior in its power to the streptococci and to other saprophytes of the intestinal tube.

The infection produced in the guinea pig by these virulent cultures is nearly always identical. The mean duration of

the infection is from fifteen to eighteen hours. At the end of two to six hours the temperature rises to 40° or 41° C. From the sixth to the twelfth hour the temperature falls to the normal, then below to 37°, 36°, 34° and even 32° at the moment of death. This is the usual thermic cycle; it is subject to numerous variations. At first the general aspect of the guinea pig is not altered; later changes appear and, in spite of the rapid evolution of the infection, the animal is considerably emaciated. The peritoneal cavity contains two to ten cc. of a thick serous exudate, very fibrinous, containing an enormous quantity of typhoid bacilli. The spleen is doubled in volume and strongly congested. The liver is fatty and of a deep red color; it is often covered with their fibrous exudate. The intestine is quite congested, filled with a fluid rich in typhoid bacilli. Peyer's patches and the mesenteric ganglia are tumefied. The kidneys are increased in volume and congested. A slight effusion in the pleural cavities may be present, and the lungs ordinarily present a very marked hyperemia of their posterior lobes. The typhoid bacillus is in a state of pure culture in the organs, the peritoneal exudate, in the blood and often in the fecal matter. Such is the picture given by Chantemesse and Widal of typhoid infection in animals. Efforts have been made by these experimenters to prevent further infection in typhoid fever patients by inoculating them with serum of animals vaccinated in the above manner. Thus far their efforts have not been successful, but it is to be hoped that if the injection be made immediately on the appearance of the first symptoms, positive results may be obtained. It has undoubtedly been noticed that the serum of animals vaccinated against typhoid infection is endowed with manifest therapeutic properties.

URGENT OPERATIONS IN OBSTETRICS.†

Dr. Bengnies, of Givet, divides surgical accouchments at term into two types—*Moderate Contraction*—from 95 to 65 millimeters; *Extreme Contraction*—below 65, that is to say, three and a half to four finger breadths. Every physician should know the breadth of his fingers, separate or together, and their length.

1. MODERATE CONTRACTION.

The fetus is dead or living, and the forceps fail. *Dead;* Cephalotripsy, craniotomy, embryotomy. *Living;* symphysiotomy.

TECHNIQUE OF SYMPHYSOTIOMY.

1. Ordinary preliminary measures, shaving, antiseptic washes.
2. Place the patient with flexed thighs, in the position of abduction.
3. Incise vertically, for a length of five centimeters, the juxta-symphyseal skin, without descending to the clitoris.
4. Separate the muscular columns on the grooved director, dividing the fascia.
5. Push back the bladder with the finger covered with muslin, and protect it.
6. Divide the inter-articular space alternately with a strong, straight bistoury and a guarded bistoury.
7. Stretch the sub-pubic ligament and divide with care, on account of the subjacent urethra.
8. Extremely abduct the thighs and separate the two bones so that the finger can move freely in the interval.
9. After extraction of the fetus with the forceps, suture the pubic with burnt silver, or silk thread, traversing the fibrous attachments on its anterior face.
10. Suture and drainage of the wound; cotton; spica bandage.

A month of horizontal rest reunites the symphysis and causes the separation of the anterior sacro-iliac ligaments to disappear. With rigorous antisepsis the operation is less grave than the Cesarean. In twenty-four cases of Spinelli, there were twenty-four recoveries for the mothers, and twenty-two for the infants.

2. EXTREME CONTRACTION.—CESAREAN OPERATION.

TECHNIQUE OF CÆSARIAN HYSTEROTOMY.

The *ensemble* of the details of the technique of Cesarean Hysterotomy com-

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

prises the *local*, *personnel*, *material*, *operation*.

A. *Local*:—Temperature at 25° C., the chilling of the peritoneum being a cause of death.

B. *Personnel*:—An assistant for the pulse (midwife); one for the chloroform, furnished with a tongue forceps; one for handling the instruments; a person to boil the solutions and towels; a physician to hold up the abdominal viscera; a supplementary aid. All should make the *hands and forearms* rigorously antiseptic by thorough washing with soap, brushing of the nails and rinsing in Van Swieten's liquid. A towel soaked in the same solution covers the breasts of the two operators.

C. *Material*:—1. Woolen blankets for the limbs of the patient.

2. A long table, covered with a latticed shutter to permit of the escape of the fluids, upon which the patient is placed asleep, the table and shutter having undergone a thorough cleansing with boiling water.

3. 150 grammes of chloroform dropped upon a compress from a dropper.

4. Silk ligature, preserved in Eucalyptol alcohol, or sublimate, 50 meters.

5. Burnt silver wire.

6. Five or six liters of salt water, 5 to 1,000, and boiled for a quarter of an hour.

7. One liter of carbolized water (50 per cent.) for the instruments.

8. Aseptic muslin formed into sponges.

9. Six soft towels well baked in the oven.

10. A pack of salicylated cotton.

11. Ten grammes of salol.

12. Idoformized and salolized gauze.

13. Antiseptic peat.

14. Large flannel body bandages.

15. Instruments: straight bistoury, guarded bistoury, grooved directors, two Volsella forceps, twenty hemostatic forceps, straight scissors, razor, various needles, rubber tube (1 meter by .005 millimeters in diameter), eight celluloid tubes. All rigorously disinfected. Irrigation apparatus. Pravaz syringe.

D. *Operation*:—This should be anticipated, and every manœuvre abstained from, even the simple vaginal touch. Operate at the beginning of labor.[1]

(1) After twelve hours of labor the cures reach forty-four per cent.; after forty-eight hours they drop to seven per cent.

1. Empty the bladder and rectum; shave the pubes and abdomen; wash carefully the field of operation; irrigate, antiseptically, the vagina.

2. Make an incision in the linea alba to the left of the umbilicus sixteen centimeters long, stopping about two finger-breadths from the pubis.

3. Pass three large sutures at the superior angle of the incision grasping the ends with hemostatic forceps. They serve to contract immediately the abdominal wound after the extraction of the fetus.

4. Bring the uterus to the center of the wound.

5. Compress the flanks in such a manner that the uterus projects strongly across the abdominal opening.

6. Make in the anterior uterine wall, well towards the middle, a vertical incision, *which is completed rapidly with the fingers, without arresting the enormous hemorrhage which boils up*. Seize the fetus by the feet through the placenta and extract it in a twinkling. If the fetus is macerated, bend the uterus without the body before opening it, and surround it with hot pads.

7. During the fetal extraction the assistants combine their movements to apply *en masse* the entire uterus against the fetus, a measure which will disengage it, prevent the escape of the intestines, and the soiling of the peritoneum.

8. Extraction of the placenta and its membranes.

9. Sponging, hemostasis.

10. Displacement of the uterus without the belly and tying of the upper sutures.

11. Compression of the neck of the uterus with the hands, the tube or a band of aseptic muslin.

12. Cleansing, irrigation, and drying of the uterine cavity.

Here the operator will consider the indications for hysterectomy, reinstallment *in situ* or castration.

A.—CASTRATION.

Indications for:—The appendages are diseased; then remove them entirely; the deformity is so considerable that it demands the stoppage of the genital function. In the latter case, ligate each tube with two threads in such a manner as to leave an occluded space in their course,

and drop them. *Total extirpation of the appendages:* Multiple ligatures of double size throughout the height of the broad ligaments, which are divided in the intervals.

B.—RESTORATION.

If the organ does not present any abnormality, nor show any trace of grave traumatism, of inertia, of profuse hemorrhage, it may be preserved and treated as follows:

1. Powder the internal surface with salol.
2. Fill it with muslin.
3. Straighten with scissors the lips of the parietal wound, if they are torn.
4. Make three tiers of buried silk sutures, mucous, muscular and musculoserous; distant a centimeter the one from the other.
5. Withdraw the muslin before closing the orifice.
6. Cleanse the wound, the circumference of the uterus, irrigate even, if necessary, the peritoneum with boiled salt water.
7. Be satisfied that hemorrhage is well staunched, and powder with salol.
8. Close the abdomen by two planes of sutures, one deep the other superficial, rendering the last firmer by the aid of a second line of large sutures, which grasped by the celluloid pegs, pleat the skin a little.
9. Upon the external wound salol, sublimated cotton, peat and flannel bandage.

C.—PORRO'S OPERATION, MODIFIED BY FRANCK, OF COLOGNE.

Indications:—Uterine inertia; putrid inflammation; uncontrollable hemorrhage.

Technique:—1. Rapid suture, by overcasting the uterine wound.

2. *Turning of the uterus through the neck, the vagina, and the vulva.*

3. Bringing down of the organ by traction.

4. Circular ligature near to the vulva.

5. Section to outer side of ligature.

6. Irrigation of the vagina and packing with salolized gauze.

This procedure is as simple and as efficacious, it appears, as the classic method is difficult, and in general, moderately good in its different results.—*Jour. de. Méd. de. Paris*, Jan. 22, 1893.

The Action of Chloroform upon the Human Being.*

Careful anatomical and pathological studies on this subject by Dr. E. Fraenkel, of Hamburg, led to the following contribution. He recognizes in long continued chloroform narcosis a dangerous poison upon the human tissues. He has been able to observe four cases, three male and one female. Two of these having died forty hours after having been respectively three to four hours under the influence of chloroform.

The third died eighteen days after having been under chloroform three hours, while the fourth died five days after the operation—the operation having consumed two and a half hours.

The author's studies in connection with the pathological changes correspond in the main with those examinations made by others on patients who have died from prolonged chloroform narcosis, in that the kidneys and liver have suffered from necrotic changes of a specific character in their parenchymal cells. Comparatively speaking, the heart seemed to suffer the least, even though this organ has never been found thoroughly intact. Up to the present date there is still a lack of pregnant symptoms which will permit of a decided opinion from a clinical standpoint on the subsequent action of chloroform; although there is after a prolonged period of chloroform narcosis an excretion of a sulphurous substance similar to cystin in the urine. Chemical and anatomical investigations have decided that the protracted use of chloroform will induce rapid retrograde changes in the organism.

The substances which are most frequently attacked are not yet clearly demonstrated; it is still an open question if its deleterious effects first attack the tissue cells of the organs in question, or if aside from this the changes in the blood lead to a destruction of the red blood corpuscles.

In closing, the author states that his studies, on both animal and man regarding this subject, have led him to think that there is a difference in the individual susceptibility which would explain the apparent freedom from its deleterious effects in some weak individuals.—*Virchow's Arch.* cxxix. 2 p. 254, 1892.

* Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

ABSTRACTS.

SATURNINE ENCEPHALOPATHY.

The fact that lead is capable of producing ill effects on the brain has been recognized from early times. Dr. Joseph O'Carroll in an article on this subject, states that it was reserved for Tanquerel des Planches, who studied lead-poisoning in the Paris hospitals between 1831 and 1839, to complete the clinical description of the various conditions which brain-poisoning by lead represents, and to unite them under the name *encephalopathie saturnine.* "The cerebral phenomena of lead-poisoning," says Tanquerel, "are delirium, coma, convulsions, accompanied perhaps by more or less sensory defect. . . . . It is a non-febrile neurosis of the encephalon of so variable physiognomy that between morning and evening, between to-day and to-morrow, the symptoms which declare its existence may change completely in aspect or in form." This rapidity of change in its symptoms is one of its principal characters. The onset of encephalopathy may be sudden, or it may be heralded for a longer or shorter time by prodromata, some of which may distinctly suggest lead-poisoning, but are so commonly unattended by head symptoms as to give us no indication of the onset of encephalopathy, while others may suggest brain disturbance without giving any hint of the cause. To the former class belong the various common phenomena of lead-poisoning, "dropped wrist," colic, arthralgia, the slate-colored line on the gums,* and a peculiarly fœtid breath; the latter group includes headache, giddiness, tinnitus aurium, diplopia or amaurosis,† together with slight intellectual and moral changes in the direction of fidgetiness, sluggishness of ideation, moroseness, sleeplessness, or unpleasant dreams.

As the combination of two or three of these phenomena—delirium, coma and convulsions—is the most frequent form of lead encephalopathy, so its prominent characteristic is, if I may say so, its inconstancy of symptoms. A case may at one visit present delirium, at another coma; to-morrow coma may have given place to convulsions, the day after the phenomena may be reversed; and each change may occur without warning, and often with extraordinary suddenness. I gather from Tanquerel that the prognosis is hopeful in proportion to the predominance of the least grave symptom, delirium, and gloomy in proportion to the predominance of convulsions. If coma persists beyond three days death is probable.

I shall not dilate upon the treatment of lead encephalopathy; it resolves itself into symptomatic and eliminatory. The latter indication is, as far as our present knowledge goes, best fulfilled by iodide of potassium; but it by no means follows that the iodide ought to be administered during the cerebral attack. If the phenomena be due to the direct action of lead upon the nerve centres, then any drug which temporarily increases the amount of lead in solution in the body-fluids would be liable to do harm. The symptomatic treatment is in no wise peculiar; but I may point to the fact that most authors, from Tanquerel to the writer in Eulenburg's *Encyclopœdia*, speak well of opium, as a clinical argument against the view which attributes this disease to a primary uræmia. Other sedatives may also be of service; the bowels, which form one of the eliminatory channels for lead, should be kept free; leeching, blistering, and various other procedures may seem desirable in particular cases. Needless to say that the patient should be absolutely withdrawn from the influences of lead.—*The Dublin Jour. Med. Sc.*

*It is interesting to note that the blue line remarked by Burton as a sign of lead-poisoning in 1840 is very fully described by Tanquerel in 1839, and had probably been noticed even earlier.

† The affections of vision which occur in saturnine encephalopathy are to be distinguished from the affections of the optic nerve (mainly atrophic) which are frequently seen in lead-poisoning; the former are central, the latter are peripheral lesions.

"I don't want any castor-oil," said a sick Boston boy, petulantly, "and I won't take it."

"Why, Horace," expostulated the mother, "don't you know that castor oil is made from beans?"

And the little boy, whose faith in his mother is perfect, took the dose, and feebly asked for more.

SELECTED FORMULÆ.

For Threatened Abortion.

Dr. E. Wilson prescribes the following with success:

℞
Tinct. opii deod..... mlx.
Sodii bromidi. ..... ʒiij.
Choral hydrate..... ʒjss.
Syr. accaciae ..... ʒj.
Aquae, q. s. ad..... ʒiij.

M. Sig.—A dessertspoonful in water every four hours.

—*Lancet Clinic.*

Ointment for Eczema.

℞
Oxide of zinc..... gr. xv.
Powdered tale,
Vegetable tar,
Vaseline, of each..... ʒv.

Sig.—Make into an ointment, and apply to the part morning and night.

—*L' Union Medicale.*

Tonsillitis.

Whether superficial or parencymatous, when recognized early, will be arrested by

℞
Tinctura Gnaici ammoniat.....
Syrupi sarsaprill. comp .....ää ʒii

M. Sig.—One or two teaspoonfuls every three or four hours.

—*Bricker.*

Chronic Rheumatism.

℞
Liq. potassi arsenitis..... ʒ ss.
Potassi acetatis..... ʒ iij.
Vini colchi rad..... ʒ ij.
Ext. cimicifuga..... ʒ iij.
Ext. phytolacca..... ʒ iss.
Aquæ menth pip..... ʒ iij.

M. Sig.--Two teaspoofuls in water every four hours.

Med. Summary.

Neuralgic Dysmenorrhœa.

Professor Parvin makes use of:—

℞
Extract. opii,
Extract. belladonnae ..... ää gr. iss.
Quinin. sulphat..... gr. xxiv.
M. Fiant pil. xxiv.

Sig.: One pill every three hours.

—*Med. World.*

Allingham's Ointment for Hemorrhoids.

℞
Bismuth subnit..... ʒi.
Hydrarg, subchlorid..... gr. j.
Morphin..... gr. iij.
Glycerini.....
Vaselini.....ää ʒj.

M. Sig.—Use in pile-pipe.

—*Ex.*

Ointment for Chronic Gonorrhœa.

This treatment may be resorted to from twice to three times a week, the sound being carried down to the point where inflammation exists.—*Ex.*

℞
Nitrate of silver crystals..... gr. viij.
Lanolin (anhydrous)..... ʒviij.
Pure olive oil..... ʒss.

M. Sig.: Dissolve the nitrate of silver in a very small quantity of water, and incorporate it with the grease. This is then introduced into the canal by means of smearing it upon a sound.

Diphtheria.

The following new combination is recommended by Ozegowski in the *Nouring Lekarskie* for diphtheria:

℞
Iodine,
Carbolic acid,
Citric acid..... ää 3 to 5 grms.
Brandy, enough to make..... 100 grms.

This is applied on cotton compresses to the diphtheritic membranes. The author believes this remedy is infalliable, and states that he has cured every case coming under his care with it.—*Medical Bulletin.*

Burns of the Eye.

Dr. Dudley S. Reynolds, for a severe lye-burn of the eye, which had first been treated with the instillation of vinegar, used, with satisfaction, the following lotion :

℞
Borate of sodium..... ʒ iiss.
Chloride of sodium..... ʒ ss.
Distilled water..... ʒ xij.
Camphor water..... ʒ iv.

—*Therap. Gazette.*

Cholera Cure.

An exchange publishes the following from a correspondent who states that $1000 was refused for it at one time:

℞
Chloroform.
Tinct. camphor.
Spts. Camphor.
Ess. peppermint.
Spt. ammon. aromat..... .....ää ʒjss.

M. Sig.--Put a teaspoonful in a wineglass of iced water, and give a teaspoonful thus diluted every five minutes.

Cystitis in Women.

℞
Citrate of potassium..... ʒ ss.
Fl. ext. of triticum repens.
Tinct. of belladona, ea c..... ʒ i.
Fl. ext. buchu..... ʒ ss.
Water add to make four ounces.

S.—A teaspoonful in a wineglassful of water three times a day.

—*Journal de Medicine de Paris.*

Hard Tooth Soap.

℞
Precipitated chalk..... ʒ ij.
Carmine..... gr. iij.
Powdered soap..... ʒ v.
Oil peppermint..... gtt. x.
Alcohol..... mxlv.

Triturate the carmine with a few drops of ammonia water and add the precipitated chalk. Dissolve the oil of peppermint in the alcohol; add the solution to the soap contained in a mortar and thoroughly incorporate; then add the precipitated chalk and when the whole is homogenous transfer to suitable molds and dry.

Corneide; An English Corn Cure.

℞
Ext. Cannab Ind..... 1 gram.
Salicylic acid..... 10 grams.
Turpentine oil..... 5 "
Collodion..... 82 "
Acetic acid concentrated..... 2 "

—*American Druggist.*

Burns in Children.

Dr. Wertheimer, of Norwich, having washed the parts with boric acid water, covers them with several thickness of gauze impregnated with a mixture of one and a half ounces each of lime-water and linseed oil, with one and three-quarters to one-half grains of thymol. At the end of ten to fifteen days this application is replaced by the following liniment:

℞
Subnitrate of bismuth..... gr. ix
Powd boric acid..... gr. ivss
Lanolin..... gr. lxx
Olive oil..... gr. xx

Apply on muslin.

—*Ex.*

Pruritus Ani.

℞
Hydrargyri chloridi corros..... gr. ij
Acidi hydrochlorici..... gtt., x
Aquæ..... ℥ viij

M. S. Apply locally, lukewarm

—*Laplace.*

℞
Argenti nitratis..... gr. xx
Aqua..... ℥j

M. S. Paint over itching surface.

—*Bartholow.*

℞
Cocain hydrochlorat..... gr. v.
Lanolini..... ℥j.

M. S. Apply locally, after washing with warm water.

—*Besnier.*

℞
Acidi carbolici..... gr. vj.
Aquæ..... ℥j.

S. M. Apply thrice daily.

—*Heath.*

℞
Benzoini, pulv. finiss..... ℥j.
Hydrargyri ammonial..... ℥ss.
Lanolin..... ℥j.

M. S. Apply twice daily. Avoid coffee, malt liquors, sugar and excess in meat.

—*Waugh.*

Treatment of Lead Colic by Large Doses of Olive Oil.

Dr. Weil, of Lyons, France (*La Semaine medicale*, No. 66, 1892), has treated five cases of lead colic successfully with large doses of olive oil. He administers a glass of the oil per diem, and in all the cases a cure was effected in three to five days, concluding with the appearance of copious stools, produced by the oil. But, before the stools, considerable diminution of the pains takes place, thus proving that, besides its action as a purgative, it exercises a certain analgesic effect upon the intestine. In one of the patients two glasses were rejected by the stomach, while the third produced an amelioration and a cure. Another patient, in whom belladonna and purgatives brought about no results, was relieved by the first glass of the oil and cured by the fifth. In all the cases of plumbism the oil not only caused a disappearance of the colic, but also of the other symptoms—myalgias, arthralgias, cutaneous anæsthesia, headache and vertigo.

Leather Bronze.

℞
Tannin..... 5 parts.
Alcohol..... 100 parts.
Gold bronze, real..... Enough.

Apply with a sponge.

Cement.

For attaching glass letters and ornaments to glass.

℞
Caoutchouc..... 1 oz.
Mastic..... 3 ozs.
Chloroform..... 50 ozs.

Mix.

For fastening metal letters on glass.

℞
White lead..... 9 ozs.
Litharge..... 12 ozs.
Linseed oil..... 27 ozs.
Mastic..... 9 ozs.

Melt the mastic and linseed oil together and gradually rub in the larthage and white lead. Use while hot.

—*Ind. Blth.*

Patent Leather Varnish.

W. R., Brookly, N. Y.—The following will, it is said, produce a varnish which will not crack or peel off from leather:

℞
Rosin..... 30 parts.
Turpentine..... 30 parts.
Oil of turpentine..... 30 parts.
Sandarac..... 60 parts.
Shellac..... 120 parts.
Alcohol..... 900 parts.
Lampblack..... 15 parts.

Digest the first six ingredients together and finally add the lamp black.

—*American Druggist.*

A Composition for Cleaning Wall Paper.

is made by mixing together 1 pound each of rye flour and white flour into a dough, which is partially cooked and the crust removed. To this 1 ounce of common salt and ½ ounce of powdered naphthaline are added, and finally 1 ounce of corn meal and ½ ounce of burnt umber. The composition is formed into a mass, of the proper size to be grasped in the hand, and in use it should be drawn in one direction over the surface to be cleaned.—*Ex.*

Removal of Mother Marks.

The *Allgemeine Medicinal Central Zeitung* gives the following as very affacious: Mix one part of tartrate of antimony with four parts of emplastrum saponatum and work into a paste. Apply the mixture to the part to be removed to the depth of one line (one-twelfth inch), and cover with a strip of gummed paper or court plaster. On the fourth or fifth day suppuration sets in, and in a few days scarcely a sign of the mark can be seen.—*Ex.*

Dose of Santonin for Children.

Dr. Demme considers the smallest efficient and perfectly safe dose of santonin to be from one-sixth to half a grain, or from one to one and a half grains a day. As a vermifuge he associates santonin with calomel, as:

℞
Santonin..... gr. iss-iij
Calomel..... gr. iij.
Sacch. lactis..... ℥ iss.

Ft. chart. No. ix. Sig.—Take one powder at six, seven and eight o'clock in the evening for three consecutive days.—*Annals of Gyn. and Obs.*

THE LIBRARY TABLE.

Diseases of the Chest, Throat and Nasal Cavities. By E. Fletcher Ingals, A. M., M. D. Second Edition. Pp. 675. 240 illustrations. New York: William Wood & Co., 1892.

This work is an excellent book for students, and contains a large amount of useful information. No space is wasted in merely collating various theories and methods suggested by different writers, as the author has confined himself to recommending the plans of treatment which have proved most efficacious in his own practice. The book is very clearly written and is eminently practical in its character. Particular attention has been paid to the question of diagnosis, the distinguishing characteristics of compared diseases being set forth in parallel columns. Dr. Ingals is fully in accord with the English authorities who look upon diphtheria as a constitutional disease with local manifestations, whilst, as he says, "many continental authors and some American writers regard it as a primary local affection with secondary constitutional manifestations."

He differs from Makenzie and some other authors in the belief that diphtheria and croup are identical, being convinced that they are two distinct diseases, in which he agrees with Aitken, who says, "any one who has seen much of croup in children, can have no difficulty in recognizing it as a disease distinct from diphtheria in its attacks, its course and results." Under the head of "Croup" he says that in children under five years of age, intubation seems to offer better chances for recovery than tracheotomy. An excellent list of Formulæ is given in the Appendix.

Disease in Children. By James Carmichael, M. D., F. R. C. P. Ed. Illustrated with thirty-one charts. New York: D. Appleton & Company, 1892.

The author in presenting this work assumes that the reader is acquainted with general medicine and the diseases of adult life. This is the first book on Diseases of Children that has ever been presented by a Scotchman and is full of quaint and peculiar Scottish expressions. The chapter on "Clinical Examination of the Child" is fully worth the cost of the work. No attempt has been made to give a detailed and systematic account of symptoms and physical signs as in lengthy monographs and treatises. The space given to each subject has been limited or extended in proportion to its importance, The basis of the book is the author's experience in public and private practice and as a clinical teacher.

The Anatomy of the Peritoneum. By Franklin Dexter, M. D. New York: D. Appleton & Co., 1892.

This little book comes to us with something new. It is a clear and concise description of the peritoneum, made very plain by a series of thirty-eight diagrams, nearly every one having a page to itself. The plates are neatly drawn and most of them are colored. Opposite each plate is a page with the description of it. The student will find this little book of great assistance in making clear the arrangement of this greatest of serous membranes.

Guide to Dissection. By Irving S. Haynes, M. D. New York: E. B. Treat, 1893.

This is a 12 mo. manual of 250 pages. It comprises three courses in dissection of three weeks each. It aims to supply the beginner with definite directions founded on practical experience in the dissecting-room, and to economize his time by being short and to the point. It seeks to answer the question, "*What shall I do next?*"

BOOKS RECEIVED.

[In sending books for notice in the REPORTER, publishers are requested for the information of the reader, as well as their own advantage, to give the price. This announcement by title will be followed, in most cases by a review, which will appear at the earliest opportunity.]

Hysterical or Functional Paralysis. By Bastaino. J. B. Lippincott, Philadelphia: 1893.

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF OBSTETRICS

For February contains a paper by Dr. Hiram Vineberg on

Pelvic Massage in Gynecological Cases.

The doctor states that he has discarded the Swedish movements employed by Brandt, for the reason that they take too much time and require the aid of a trained assistant, and also, that he considers his results to be as good without their aid. He employs other methods besides pelvic massage for certain conditions—for instance, a medicated tampon is often placed behind a retroverted uterus. He advocates the treatment by massage for the residua of inflammatory processes, thickened uterine ligaments, adhesions, and displacements of the uterus, tubes and ovaries. Simple enlargement of the tubes he does not consider a contra-indication, but when the tubes contain pus or there is an acute inflammatory condition present, the treatment is dangerous. As one would expect, he has no success in complete prolapsus, but states that massage applied to a uterus that is simply low down in the pelvis, often gives good results. He claims to have been able to have effected an ideal cure in about fifty per cent. of the fifteen patients treated. Incidentally, he makes a remark as to the improper use of pessaries. He has removed pessaries from cases in which the ovaries were swollen, tender and fixed—cases in which it were a criminal act to have introduced one. But after the uterus has been freed from its adhesions and the ovaries replaced by massage, the pessary was well borne and did good service. He considers the objections urged against the procedure, and particularly the one so often urged—the production of sexual excitement, and denies that such is ever the case if the manipulations are properly performed. The paper includes the report of the cases the author has treated in this manner.

Dr. Julius Rosenberg considers the subject of "Accidental Hemorrhage" during labor, with the report of several interesting cases. The author believes the most frequent cause to be a pathological condition of the placenta either from general disorders as syphilis or nephritis, or local inflammatory changes in the uterus, though traumatism is also undoubtedly a cause. The diagnosis and treatment are discussed and the tampon condemned as converting the case into one of concealed hemorrhage. The recent literature on the subject is carefully reviewed.

Dr. Christian Fenger, in an article on the "Total Extirpation of the Vagina for Carcinoma," describes an operation recently performed by him for the relief of this rare condition. The patient whose case is reported in full in the article, unfortunately had a recurrence of the disease for which no relief could be afforded. The subject of primary vaginal carcinoma is carefully considered and the article illustrated with cuts of the operation and of microscopical sections of the tumor removed.

Dr. A. Palmer Dudley contributes an article on

Umbillical Hernia in the Female,

reporting five cases. In the operative treatment of the condition he condemns the use of catgut supporting sutures on the ground of the uncertainty of its absorption. In closing such hernia he opens the sac and frees all adhesions. The sac wall is then dissected from the cellular tissue, cut away and the peritoneum closed by a continuous catgut suture. The two halves of the linea alba are then dissected out and brought into close apposition by a second continuous catgut suture. After this, silver wire sutures are introduced through the linea alba, including at least one-third of an inch of the muscle in each suture. Each suture is shouldered, over the cut surface, after the manner of Dr. Emmet in his perineal sutures. "Over each suture a short canula is adjusted, pressed down firmly on upon the suture, and held in position by a perforated shot upon the wire suture at the upper end of the canula. Cellular tissue and skin are then closed with interupted salmon gut sutures, allowing the canula with their enclosed wire sutures to protrude between the cut surfaces about half an inch above the skin." The author states that no ill effects followed the use of the canula, although in one case they were allowed to remain with their silver wire sutures for almost a month. In discussing the cause of ventral hernia, he points out that they are much more frequently met with since the advent of laparotomy for pelvic disease. The cause is carelessness in the closure of the wound ; unnecessary and prolonged use of the drainage tube ; an unnecessarily long incision ; too early removal of sutures and the neglect to wear a properly fitting bandage after operation. The paper is illustrated with cuts of the hernia and the method of applying the silver wire sutures and canula.

Dr. W. S. Christopher discusses the

Treatment of Summer Complaint,

dividing the disease into two broad classes, characterized by sour or putrid stools and due to the fermentation respectively of carbohydrates and of proteid matter taken as food. The treatment is conducted on the following lines: 1. Maintaining the strength of the child. 2. Removal of the intestinal contents. 3. Regulation of the diet. 4. Administration of intestinal antiseptics. 5. Combating the special symptoms. For the removal of intestinal contents he advocates calomel in three doses of four grains each, at intervals of four hours. Lavage of the bowels he also considers a valuable means of quick evacuation of the intestinal contents. The question of diet is also entered into and, if the author's ideas as to causation be correct, it is

evident that when the stools are putrid the carbohydrates are to be withheld, and albuminoid materials if sour stools are present. Sterilized milk he thinks of value in the prophylaxis of summer complaint, but not in its cure. Subnitrate of bismuth, in his opinion, approaches more nearly to an ideal disinfectant of the bowel than any other drug. It must be used freely in doses of ten to twenty grains, from three to five times daily. Water internally and by baths he considers of great importance. The drinking water should be sterelized. Opium he considers a much abused drug and rarely uses it.

Dr. J. Edwin Michael considers the subject of "Symphysiotomy," reporting a successful operation on a rachitic negress. He advocates the procedure especially in face presentations when the chin becomes locked posteriorly. Dr. R. P. Harris's table of operations during 1892 is appended to the paper.

A similar paper is that of Charles P. Noble on

The Caesarean Section and its Substitutes.

The Porro and Sanger operations; symphysiotomy and embryotomy are contrasted. Embryotomy on the living child is condemned and symphysiotomy or the Caesarean section should be substituted for what he characterizes as murder. His conclusions are that the Caeseran section in typical cases is a safe operation, but should be performed before labor has set in, or during the first stage. The classical operation is to be preferred to puerperal hysterectomy in typical cases, in that it preserves the fertility of the woman, and the mortality of a second operation is no greater than the primary one. Puerperal hysterectomy is preferable in cases seen late, where infection or atony of the uterus is to be feared, or in cases complicated by large fibroid tumors. Symphysiotomy will probably supersede Cæsarean section done for the *relative indication.* Embryotomy is no longer justifiable on the living child as an elective operation.

Dr. Howard A. Kelly presents the "Ethical Side of the Operation of Oophorectomy," publishing the letter of a clergyman, the husband of a patient, or the subject. His correspondent takes the ground that "nothing short of impending death justifies the operation."

PRACTICE

for January contains the report of three clinical lectures. In the first, by Dr. William Goodell, on

Dysmenorrhoea, Menorrhagia and Leucorrhoea.

the author advise the use of the dilator for the relief of the dysmenorrhœa, followed by curetting of the uterine cavity if menorrhagia be also present. The dilation serves to straighten and enlarge the cervical canal, thereby removing the cause in obstructive dysmenorrhœa. After the curetting the uterus is douched with 1 to 2000 bichloride of mercury solution, and packed with a strip of iodoform gauze. Dr. Goodell states that he has never seen any ill effects follow this treatment. Thorough curetting of the uterus is advised in cases of leucorrhœa of uterine origin. The presence of tubal and ovarian disease is, of course, a contra-indication to this treatment.

[Dr. Goodell's position in regard to the harmlessness of dilitation has been freely criticised, and tubal and ovarian disease is said to follow in many instances, necessitating a subsequent section and removal of pustubes.—ED.]

The second lecture is by Dr. Henry C. Coe on

Pessaries.

Pessaries, like other surgical supports, should fit; otherwise they are useless and much of the loss of confidence in them comes from neglect of this rule. Another cardinal point is that they are not used to replace a prolapsed uterus, but to keep it in position after it is replaced. If the patient has prolapsed and fixed ovaries or painful pelvic masses, a pessary cannot be worn on account of pain, no matter how well fitted. The uterus is to be replaced by the fingers in the vagina, with the patient in the knee-chest position and without the use of the sound. The instrument should fit accurately and give no pain to the wearer.

The third lecture is by Dr. A. M. Phelps on

Bond's Operation for Talipes Varus.

"The operation consists in making transverse incisions with a Pacquelin cautery, beginning at the inner malleolus and extending one-third of the distance across the sole of the foot, cutting through the cellular tissue down to the muscles." About four incisions suffice—two semi-circular incisions crossing the transverse. The lecturer believes that if the arch of the foot were well shoved up in place, and retained there by a plaster-of-Paris dressing for a few weeks prior to operation; the latter would be more effectual. He considers it much more scientific to thus shorten the girders of the sole of the foot than to do an osteotomy.

THE OPHTHALMIC REVIEW

for January opens with a paper by Sydney Stephenson upon "The Surgical Treatment of Trachoma." He writes in favorable terms of two operative procedures, namely, "expression" of the morbid material and excision of the conjunctival *cul-de-sac.* For expressing the peccant material he uses two kinds of forceps: First, ordinary stout dissecting forceps, and, second, roller forceps modified from Knapp's pattern. The rollers are nine or ten m. m. in length, that is to say, about half the length of those in Knapp's model, and the cylinders are larger in diameter than Knapp's.

This article is followed by a review of a remarkable work by W. Schoen (Leipzig) on

The Functional Disease of the Eyes; the Causes and Prevention of Cataract and Glaucoma

In some important particulars the author's views upon the Physiology and Pathology of Accommodation and Convergence differ from those generally accepted. He claims especially to demonstrate that during accommodation the contraction of the ciliary muscles causes an increased pressure on the whole surface of the vitreous body, and hence an increased tension in the zonula. The tightened zonula, pulling in a somewhat backward direction on the margin of the lens, increases the convexity of this latter. Thus the united mass of lens and vitreous is compressed by the contraction of the ciliary muscle and changes its globular form into an egg-like form, and the increased convexity of the lens is a part of this change. The review remarks that the alleged increase of vitreous pressure during the act of accommodation is purely hypothetical, and its amount must in any case be extremely small. Careful manometrical experiments on the eyes of animals during the electrical induction of the accommodative act, have failed to detect the slightest change of pressure either in the aqueous or vitreous chamber. Schoen seems to consider that cataract and glaucoma are primarily due to "strain" from uncorrected anomalies of refraction, accommodation and convergence, believing that both diseases may be averted or arrested by the use of proper spectacles. He expresses but little faith in iridectomy as a cure for glaucoma. The book contains three hundred pages and advances much debatable matter. In the words of the reviewer "it represents a vast amount of earnest labor and shows an intense and enthusiastic conviction on the part of its author. We are bound, however, emphatically to express the opinion that the elaborate theories which pervade it are to a very large extent fallacious."

H. Dor (Lyon) has an article

On Contact Lenses.

The author describes the contact glasses introduced by Fick, of Zurich, in 1888. Working on the idea that it was necessary completely to eliminate the action of the cornea, Fick replaced that structure by a glass shell possessing the normal curvature of the cornea. This mask was applied directly to the eye, and the space between it and the cornea was filled with fluid of the same index of refraction as the aqueous humour. After many trials, Fick selected a two-per-cent. solution of grape sugar as most suitable for this latter purpose. Fick's most improved glass had a radius of curvature of 8 m. m., in order to correspond to that of the natural cornea; while a wider part, having a radius of 15 m. m., was constructed to rest upon the scleratic and thus to support the corneal part of the lens. With this lens Fick obtained satisfactory results. Benzoni, an optician of Geneva, has recently succeeded in constructing satisfactory contact lenses, which cost forty francs apiece. Dor finds that the use of these glasses is not very agreeable to the patient, although cocaine renders them tolerable. It is not difficult to place the lens in position, but the introduction of liquid between the glass and cornea is somewhat troublesome. Dor's first patient suffered from conical cornea and central corneal opacity and had double iridectomy performed for the relief of these conditions. Sight of the left eye equal to $\frac{20}{70}$ with a hyperbolic lens, with a contact glass and minus 5 D spherical, the patient recognized $\frac{20}{60}$ and No. 2 Snellen. The patient wore the contact lens for three hours without discomfort. Dor gives a table of five patients upon whom he tested the contact lenses and remarks that the greatest improvement took place in cases of hypermetropia. He concludes thus: "To sum up the contact glass of to-day is not very easy to apply, and renders true service only in irregular astigmatism of considerable amount and in cases of conical cornea."

ANNALS OF OPHTHALMOLOGY AND OTOLOGY.

In the January number of the *Annals* is a contribution upon "Blood effusion between the Retina and Viterous Body" by Dr. F. C. Haltz, of Chicago. In all three of the cases reported vision was perfectly restored. This is followed by

"The Relative Importance of Astigmatism in the Production of Asthenopia."

Second Paper by Dr. Risley. Much of this paper is taken up with the consideration of "what is to be regarded as the refraction of the normal eye." We should have thought that this question had long ago been settled, and we are therefore not surprised that our author should conclude by saying "that the emmetropic eye is not only the model, but the normal eye." Referring to the use of the ophthalmometer he writes, "that it removes the necessity for mydriatic corrections, does not in a very large group of cases accord with my experience." In very many cases the astigmatism is quite accurately estimated both as to the degree and the direction of the principal meridians of corneal curvature; but alas! in very many others its findings are approximations only in both respects, while in others the astigmatism, if in low degree and especially if "against the rule," is entirely overlooked.

Under the title "Does Homatropine, as generally used reveal the whole error of refraction," Dr. W. F. Coleman reopens the vexed question of the reliability of Homatropine as an efficient mydriatic. His experience, as elaborately tabulated, seems conclusively to show, that it is not absolutely reliable even when it is combined with cocaine, in the form of discs and the applications frequently repeated.

In another part of this number is a paper by Dr. Stannard in which he denounces the practice of determining the correction of hypermetropia and hypermetropic astigmatism without the previous use of a Mydriatic, and he considers that "homatropine and cocaine discs containing of each $\frac{1}{50}$ of a grain efficiently paralyse the accommodation." "By the use of one to three of these discs in each eye within 90 minutes, in the majority of cases we may sufficiently overcome the spasm of accommodation."

PERISCOPE.

THERAPEUTICS.

Cocillana—An Interesting Addition to the Materia Medica.

Respiratory inflammations always form a large proportion of the physician's cases. A Bolivian remedy which gives promise of much therapeutic efficacy is Cocillana, which was introduced a few years ago through the researches of Professor H. H. Rusby, the eminent botanist.

Experiments were made with it by many medical investigators, who found its action very satisfactory in catarrhal inflammations of the respiratory organs, in croyza, hay asthma, bronchitis, acute and chronic, influenza, and pneumonia.

It possesses also laxative and purgative qualities, and has been employed successfully as a substitute for ipecac and apomorphia in catarrhal conditions.

MEDICINE.

Duboisine in the Treatment of Hystero-epileptic Convulsions.

Quinine and more recently antipyrine have been recommended in the treatment of the convulsions of hystero-epilepsy. Dr. P. Albertoni, Professor of Physiology at the Medical Faculty of Bologna, now advocates the use of hypodermic injections of half a milligramme (grain $\frac{1}{180}$) of sulphate of duboisine in the treatment of the same affection. He has employed these injections with success in three cases. In the first of these the administration of morphine and antropine had produced no effect on the convulsions which were very violent. They, however, disappeared after two injections of duboisine and since that time, a period of five months, the patient has only had two more attacks, which coincided with the menstrual epoch and readily subsided under the administration of a single injectien of duboisine. The other phenomena of hystero-epilepsy, however, remained unaffected. In the second patient the convulsions also rapidly disappeared after a few injections. The same result was obtained in the case of the third patient but here the administration of duboisine was apparently followed by an exaggeration of the cardiac palpitations from which the patient had suffered previous to the application of the treatment. —*Med. Week, Paris.*

How to Treat Those Who are Overcome with Gas.

1. Take the man at once into the fresh air. *Don't* crowd around him.
2. Keep him on his back. *Don't* raise his head or turn him on his side.
3. Loosen the clothing at his neck and waist.
4. Give a little brandy and water—not more than four tablespoonfuls of brandy in all. Give the ammonia mixture (one part aromatic mixture to sixteen parts of water) in small quantities at short intervals—a teaspoonful every two or three minutes.
5. Slap the face and chest with the wet end of a towel.
6. Apply warmth and friction if the body or limbs are cold.
7. If the breathing is feeble or irregular, artificial respiration should be used, and kept up until there is no doubt that it can no longer be of use.
8. Administer oxygen.—*Med. Times.*

NEWS AND MISCELLANY.

U. S. ARMY FROM FEBRUARY 12TH TO FEBRUARY 18TH, 1893.

Leave of absence for three months, on surgeon's certificate of disability, with permission to leave the Department of Texas, is granted Major James P. Kimball, Surgeon, U. S. Army.

Leave of absence for one month is granted 1st Lieut. Isaac P. Ware, Assistant Surgeon, U. S. Army.

Col. Joseph R. Smith, Assistant Surgeon General, U. S. Army, granted two months' leave, with permission to leave the United States.

Major J. V. D. Middleton, Surgeon, will, in addition to present duties as post surgeon of the Presidio, of San Francisco, Cal., perform the duties of medical director, Department of California, during the absence of Colonel Joseph R. Smith, Assistant Surgeon General, U. S. Army.

First Lieut. Frederick P. Reynolds, Assistant Surgeon, is relieved from duty at Fort Monroe, Va., and assigned to duty at West Point, N. Y.

Par. 1, 2 and 4 of S. O. 34 A. G. O., February 14th, 1893.

The suspension of the order assigning Captain Eugene L. Swift, Assistant Surgeon, U. S. Army, to Fort Yates, North Dakota, is removed.

To the Inauguration Via B. & O. R. R.

The Baltimore and Ohio Railroad announces that on the occasion of the Inauguration of Cleveland and Stevenson on March 4th it will sell excursion tickets to Washington and return at low rates. Tickets reading via the B. & O. will be on sale at its own offices and at the offices of the principal railroad companies throughout the country. Tickets will be sold March 2d, 3d and 4th, and will be good for return journey until March 7th inclusive. For information in detail concerning time of trains, rates of fare, etc., address C. P. Craig, Gen'l Eastern Passenger Agent, 415 Broadway, New York; A. J. Simmons, New England Passenger Agent, 211 Washington Street, Boston, Mass., or James Potter, District Passenger Agent, 833 Chestnut Street, Philadelphia, Pa.

NATURAL AND ARTIFICIAL DRYNESS IN CHAMPAGNE.

Natural dryness and the smallest percentage of alcohol constitute the purest and most wholesome champagne, as compared with artificial and spirituous dryness, which admits of a higher percentage of sugar in the wine, while giving a dryer but false taste, as is the case with several of the so-called "brut" wines. By chemical analysis of Prof. R. Ogden Doremus, G. H. Mumm's Extra Dry contains, in a marked degree, less alcohol than other prominent brands, and he recommends it, not only for its purity, but as the most wholesome champagne. These properties and its remarkable quality and natural dryness have made it the most popular, as is evidenced by Custom House statistics of 1892, showing G. H. Mumm's Extra Dry imports to be 75,880 cases, being more than one-fifth of the entire importation and over 9,000 cases more than of any other brand.

FIRWEIN! The Ideal Expectorant

WHY?

1. IT CONTAINS all the essential ingredients to relieve Coughs.
2. IT IS COMPOSED of the Balsams associated with Phosphorus, Iodine and Bromine.
3. EXPERIENCE has verified the effectiveness of the combination.
4. IT CAN BE GIVEN IN ALL cases where Cod Liver Oil is prescribed.

DISEASES

where prescribed and found unsurpassed.

ACUTE AND CHRONIC BRONCHITIS

LARYNGITIS,

PNEUMONIA,

ASTHMA and

PULMONARY TUBERCULOSIS

DOSE: One or Two Teaspoonfuls before meals, or oftener, regulated by age or disease

FORMULÆ: Each fluid drachm contains Phosphorus 1-100 of a grain; Iodine, 1-6 of a grain; Bromine, 1-6 grain

Prepared only by **THE TILDEN CO.**

ESTABLISHED 1848
INCORPORATED 1893

INVOLUTION FORM OF THE TUBERCLE BACILLUS AND THE EFFECT OF SUBCUTANEOUS INJECTIONS OF ORGANIC SUBSTANCES ON INFLAMMATIONS.

SAMUEL G. DIXON, M. D.

Prof. Robert Koch announced in 1882 the discovery of the cause of Tuberculosis. He claimed that comsumption was produced by a *peculiar bacillus of a special shape.* This he described as a rod-shaped micro-organism with rounded ends, either straight or curved, and frequently beaded. This simple form was accepted as a constant character until the summer of 1889, when I first observed, in an artificial culture on an Agar Agar glycerin nidus, a slight inclination to bud in one or more places along the rod, without the production of any particular angle, some relations forming an acute while others formed a right or possibly an obtuse angle. A single bud could only be recognized with a high power objective focused and illuminated with particular nicety. The indications, however, were so often repeated in each field as the slide was moved upon the stage of the microscope, that I was sufficiently convinced of the presence of branches to review the life-history of the tube in which they were found and to speculate upon the factors likely to have brought about the evident volution. The result was the production of germs with decided *branches,* some of which were quite as long as the parent rods or stems.

This result was published in *The Medical News* of October 19th, 1889. In 1891, Prof. Allen J. Smith observed branched forms of tubercle bacilli in human sputum. Since then Prof. Klein, Herren Fischel, Mafucci et al., have described the branching of this germ. In the summer of 1892 I observed the bacillus in this cycle of life in the liver of the Green Jay of Mexico, *Xanthoura luxosa.* This discovery, coupled with my observations of 1889, and corroborated by the statements of other scientists, must now compel the bacteriological world to recognize a more complex form of the tubercle bacillus than that observed by the great German bacteriologist in 1882.

Since the discovery of the branched form of the tubercle germs in 1889, I have been able to continuously reproduce them on artificial mediums. While the young germs seem to be quite simple in form, appearing in straight rods and rods bent upon themselves, those which have arrived at the age of four weeks, particularly in the presence of an excess of glycerin and in a temperature of 40° C., become branched. The young bacilli, when introduced into the animal tissues, produce tuberculosis, while the older cultures gradually lose their virulence, in all probability owing to their inability to reproduce themselves. This fact indicates that the branched form represents an involution life-cycle of the germ. Notwithstanding the fact, however, that the devitalized,

*Read before the Academy of Natural Sciences, Phila., Feb. 21, 1893.

dying or dead bacilli cannot produce consumption, they, with their products, effect a decided increase in tubercular inflammation, which inflammatory process even results in necrosis of the tissues.

These phenomena led to investigations proving the correctness of the hypothesis first published in my Monograph on Immunity (*Medical News* of Oct. 19, 1889) to wit: "It is possible that, by a thorough filtering out of bacilli from tuberculous material, a filtrate might be obtained and attenuated so that by systematic inoculations a change might be produced on living tissues that would enable them to resist virulent tubercle bacilli." In this line of experimentation I proved that the presence of the germs was not necessary to produce the hyper-inflammatory condition of the tuberculous tissue but that it was a *product* of the bacillus that caused the reaction upon the tuberculous animal tissues. This, since called *Tuberculin* and introduced into the human economy for the purpose of curing tuberculosis, when introduced into animals suffering with artificially produced tuberculosis, often destroyed the condition called consumption and in many cases appeared to produce immunity to the poison of tuberculosis. The process, however, was not quite so successful in animals which had contracted tuberculosis through one of the natural channels. In these cases, tissues surrounding that which was recognized as tuberculous afterward became infected with consumption.

While this was and still is discouraging we have good reason to believe that *Tuberculin* will be permanently established as a remedy for this pathological condition. The toxic albumose causing inflammation of tissues markedly tuberculous, coupled with the fact that it is found in such tissues, led me to inquire whether or not some other constituents of animal tissues, pathological or normal, would produce reaction if introduced in excess into the general circulation. This line of experimentation was begun by first using an albumose of the goat, a comparatively immune animal. This material, however, if at all active as a remedial agent in tuberculosis, is so slow in its effects that I have heretofore failed to produce any marked changes. When, however, in the course of my investigations I overloaded the animal system with some of its waste products, Dr. William L. Zuill, M. D., D. V. S., who has kindly carried on the clinical work on animals for our Bacteriological Laboratory, reported in the *Times and Register* of Sept. 26th, 1891, a reaction by the Amide group on inflammatory tissues, the animals experimented on being tuberculous. As this group included that which we believe to produce the inflammation of gout, I was led to review my experience with tuberculosis in relation to lithemia. Studying this field with the lithemic and tuberculous habits in view, I was soon impressed with the fact that when these diseased conditions were present at the same time in any individual we could claim it to be an exception to the rule.

To determine the special action of the Amide group upon inflamed tissues when introduced into the circulation, a case of Lupus vulgaris was selected and first treated by the subcutaneous introduction of .03240 Gm. of Kreatinin, alternated twice weekly with .130 Gm. of Taurin, urea and uric acid. The average temperature during treatment was slightly raised, though not to any very marked degree, under the influence of such small doses. The more recent patches of lupus, however, became markedly inflamed, being accompanied with a burning sensation. On the third day after the first injection, a marked granulation could be detected around the outer edge by the aid of a strong amplifying pocket glass. This apparently healthy granulation has continued for ten days, in which time the patch has one half of its original area healed. The result shown at this early stage of the experiment is sufficiently encouraging to warrant not only a continuation of the treatment in this case, but in other forms of tuberculosis.

The only other subjects upon which these injections have been tried have been cases of pulmonary tuberculosis in a very advanced stage, where there was too much lung-tissue already destroyed to warrant the expectation of a favorable result. The fact that we apparently have an action on the lupus and no marked result with *small* doses on advanced cases of pulmonary tuberculosis causes me to realize that the line of experimentation must not be confined to tuberculous inflammation, but extended to the action of these organic substances on the entire group of inflam-

matory growths, the effect being produced possibly, by supplying that in which the pathological tissues are deficient.

This line of inquiry, which had its origin in Bacteriological Laboratory of the Academy, has opened up a new and wide field of important scientific medical investigation. The main object of this communication, at this time, is to confirm the original discovery of the *branched form* of the tubercle bacillus by recording the observations of the same life-cycle of that micro-organism found in animal tissues. I have, however, ventured to advance theories and results regarding the action of substances far removed from the bacillus, because they were suggested during my studies of the branched form of that organism.

THE APOTHEOSIS OF DIRT.

WM. H. LINK, M. D., Petersburg, Ind.

When St. Paul first entered the city of Athens, the most striking object to greet his eye was the altar erected to the Unknown God.

The intellectual Athenians having personified every passion, every science and every art, and assigned to each its presiding deity, thought to further promote their own welfare by appealing to the unknown, at the same time in doubt whether they should invoke its beneficence or propitiate its power.

The principle of worshiping the unknown and deifying the mysterious was not peculiar to Athens; nor was it either lost or forgotten during the Dark Ages.

Imagination, the most potent faculty in the advancement of man along any line of achievement, like all power may become potent for evil as well as for good. For "the lunatic, the lover and the poet are of imagination all compact," and whenever "it is a condition and not a theory that confronts us," the theory appealing to the imagination finds its priests ready to serve at the altar whatever be the doctrine.

The history of medicine in its advance from the crudest empiricism of the Egyptians to the brilliant and startling triumphs of Jenner, Pasteur, Lister and Koch, furnishes numerous examples where the imagination, disdaining facts and scorning experience, ran riot with the truth and turned back the wheels of progress.

The mutations of time cannot destroy the golden thread of truth running through all the cycles of medical hypothesis in which working theories are invented by the few and embraced or rejected by the many. While this golden thread is lengthened out from age to age there is its complement of error running in parallel lines. Error being always bolder, more positive and certain than truth, it follows that the medical millenium is very far off when the devil of prejudice and ignorance shall be chained for a thousand years.

It is a peculiar fact which shows the slow advance of scientific knowledge among the masses, that about the time the profession have discarded some theory or abandon the methods growing out of it, the laity will usually have just begun to adopt its worst features and to embrace them with a zeal born of discovery.

The history of the clumsiest practices arising from the wildest theories may be traced in the methods of the common people, who are ever at least an age behind the profession. We often smile at the wise suggestions of some neighbor or old woman, made with all due solemnity, and supposedly in the interest of the patient whom we at the time may be treating. Yet if we would only look backward a few decades, we might find in the teachings of the profession plenty of authority for what the old woman or officious neighbor advocates. All of us in country practice, can recall the many filthy recipes foisted upon the sick in our absence, such as the famous "sheep nanny tea" for measles, urine for "thrash," rattle-snake and earth-worm oil for rheumatism, dog meat for consumption, and dried horse-dung as a styptic application for freshly incised wounds.

There was a time, not long past, when tincture of hog-lice and like delicacies were prescribed by the profession with a firm faith in their healing virtues, on the

principle that the more nauseating and filthy a thing, the more certain and striking its therapeutic results. The omniscient genius of Shakespeare has amply illustrated the confidence reposed in the power of such concoctions for good or evil. In Macbeth, he describes the witches' brew, in which the dynamic influence of the incongruous elements was intensified by the mysterious mummery of enumerating

> "Fillet of a fenny snake
> In the caldron boil and bake;
> Eye of newt, and toe of frog,
> Wool of bat, and tongue of dog,
> Adder's fork, and blind-worm's sting,
> Lizard's leg and owlet's wing,
> For a charm of powerful trouble
> Like a hell-broth boil and bubble."

Our homeopathic brethren yet appeal to the imagination of their followers with triturations and solutions of snake poison and tarantula juice, while we regulars occasionally prescribe Blatta orientalis with a like result, if not from like motives.

On this principle we can understand why any doctrine, whose foundation is cleanliness and whose gospel is purity, has such a struggle with error and such a fight with prejudice. "Ashes to ashes, and dust to dust," is a sentence passed upon all creatures alike, but too many try to execute the sentence upon themselves ere they "shuffle off this mortal coil."

These ideas, prevalent as they are among the major part of humanity, are not likely to produce any effect beyond emesis so long as they are confined in their application to the internal medication of the sick.

It is when applied to the practice of obstetrics and surgery that disaster follows in their wake.

It is the presence of crude notions, the distribution of ignorance and superstition, the influence of the mysterious and the hold which precedence has upon the imagination that enables midwives to ply their calling, even in localities where enlightened and scientific physicians abound.

In the natural world phenomena constantly occur which are paralleled by close analogies in the moral world. Geology tells us that in the great cataclysms of past æons where whole genera have become extinct, there is often a single species left to call attention to the myriads that have become destroyed or that have disappeared in the ordinary course of evolution. Reasoning in this way some of our naturalists suppose the great modern sea serpent is nothing more nor less than a last remnant of those ancient monsters that swam about in prehistoric seas as gigantic sea-lizards. The botanist is sometimes agreeably surprised to find a plant representative of the carboniferous ages when gigantic ferns left their skeleton markings in the buried coal measures.

In the same way the midwife and the faith doctor stand to-day — living representations of that mythological period in medicine when tom-toms, artificial thunder, and various preparations of filth and venom banished disease whether the demoniac or some other equally absurd pathological theory obtained. As the midwife was then she is to-day. As she is in one locality she is in another. Even now when medical schools have thrown open their doors to women and men alike, the midwife exists with the divine attributes of ubiquity and immutability. She is the same yesterday, to-day, and forever, and she is everywhere offering and giving her services to rich and poor, high and low. Thus

> "With equal pace impartial Fate
> Knocks at the palace and the cottage gate."

The streptococcus of erysipelas, the staphylococcus pyogenes—both aureus and albus, the bacillus of Lœfler all laugh when she appears, for they recognize an old friend who is to transplant them to virgin soil. The gonnococcus of Neiser has been known to "prove up" on a quarter section of her vagina, and larger bugs like the pediculus pubis and the pediculus vestimentorium have been reported to have "staked out a claim" on her person, while she is always "at home" to that noble old Roman family the Cimex Lectularii.

She is one who is graduated into her calling by a variety of circumstances and a number of qualifications.

There is usually in every community some old woman who has a husband to partially support. Being poor and ignorant she is ready to half eke out a meager subsistence by turning her hand to any little odd jobs around the neighborhood. She "cleans the guts" at hog-killings for half the soap-grease. If any old sheep of a neighbor farmer dies, just as soon as it gets ripe enough for the wool to slip, she picks it on the halves. For these and other reasons, she soon has a reputation as one whose stomach nothing can turn.

Having once established a character of this kind she is immediately in great demand for dressing any specially virulent old sore or ulcer which persons in her vicinity may happen to possess. She not unfrequently has some wonderful salve which will do most anything from drawing a nail or splinter out of the foot to "healing all burns without a scar." The basis of this ointment is always both cheap and nasty, being most often the excrement of some one of the domestic animals; the favorite menstruum is usually goose grease and the corrigens and adjuvans may be anything from elder-bark to fried "cow-cumbers."

When anyone near her dies she is always the first one called upon to wash and lay out the corpse. Finally the time arrives when she is to meet the crowning triumph of her life, to put the cap-sheaf on her career, to add a new laurel to her wrinkled brow—the final accolade, to which all her other experiences have been gradually but surely leading her, and for which they have been just as certainly and thoroughly preparing her. Some woman in labor hurries up, or the doctor is delayed, and the child is ushered into the world with no help but Aunt Handy, who at one bound has become a mid-wife, with all that the name implies. She cuts the cord, smears the stump with some of her favorite salve and then proceeds to make the mother comfortable by taking a pull on the part of the cord left hanging out of the vagina, while kindly having the patient walk around the room to assist nature as much as possible. In order to save the bed she puts some old dirty quilt under her charge, while a due regard to her clean linen causes the patient to go through the parturient process dressed in clothing that nothing can soil.

Our newly fledged midwife has several qualifications soon added to those vouchsafed her by the long course of training she has undergone, which give her peculiar strength in a way. Having suddenly become what her ambition had long led her to hope for, she "fixes up" for the business. Heretofore her wardrobe for state occasions consisted largely of a calico dress. But it had one defect, it showed dirt, and had to be washed once or twice ere it succumbed to the ravages of time and travel. She now invests in something "all wool and a yard wide" which will not *show dirt*, and which may be worn for years without washing. This being her "Sunday-go-to-meetin' dress" she wears it only when laying out the dead, nursing some bad case of erysipelas or child-bed fever, or when waiting on a parturient woman.

Her hands are hardened by toil and seamed by exposure, and her nails being useful in picking wool and doing other labor, are not always "trimmed to the quick" nor free from a suspicion of real estate. Handkerchiefs not being plentiful in her wardrobe, she wears a long apron to protect her dress and to wipe her hands and blow her nose on. The latter act she deftly robs of its poetry by turning the under side to the front and depositing the accumulated secretion of the schneiderian membrane on the part of the apron thus newly exposed; she then gives it a rub or two between thumb and fingers in order to spread it over as much surface as possible, for drying if not for cosmetic reasons. The apron is then dropped till necessity compels her to repeat the performance.

Being thus equipped she is at once the personification of filth, the apotheosis of dirt, the concrete exponent of ignorance and the coëfficient of sepsis. She ought to be suppressed by law unless she will become properly educated for a correct and safe discharge of her responsible duties. When she is thus instructed she will be an accomplished physician; for the very highest medical knowledge and skill are essential to a proper and safe discharge of the duties devolving on the obstetrician; and it is utterly impossible for an ignorant and half trained mind to grasp even the science of the mechanism of labor, much less the many physiological, pathological and other questions which pertain to parturition.

We often hear that a young man has the ability to carry on a certain line of business. If carefully analyzed we believe this ability will be found to consist of

1. Honesty.
2. Industry.
3. Economy.
4. Sobriety.
5. Consistency.
6. Prudence.

The last of these will prevent him from investing in an outside enterprise unless he can afford to lose the money should it prove a failure.

CLINICAL LECTURES.

GYNECOLOGICAL CLINIC, BUFFALO GENERAL HOSPITAL.

MATTHEW D. MANN, A. M., M. D.

DYSMENORRHŒA.

A young woman comes before us suffering with dysmenorrhœa. The case has proved intractable and it is one of true dysmenorrhœa, the pain being due to the menstrual function. I want you to start in practice with the idea that all the pains which a woman may suffer at the time of menstruation are not the pains of dysmenorrhœa. I recall a case of ureteritis accompanied by continual pain which became intolerable at the menstrual epoch. Such pain accompanying but not directly due to menstruation should not be called dysmenorrhœa.

Menstruation may be defined as a periodical loss of blood from the uterus and, therefore, the pain of dysmenorrhœa must be due to a cause in the uterus itself. In this case the pain never disappears during the menstrual period, but it is increased at times and there are occasional exacerbations of pain with spasms.

On making an examination I find that the uterus is acutely anteflexed and, on passing a sound into its cavity, I meet with a distinct constriction at the internal os. This is not due to flexion for when I straighten the uterus the instrument still passes with difficulty and "jumps" over an obstruction at the internal os. The passage of the sound causes great pain, especially as it touches the internal os. The patient has a few little clots come away at each menstruation and it is their passage over the supersensitive mucous membrane in the vicinity of the internal os that causes the exacerbations of pain.

Having this definite anatomical basis for the dysmenorrhœa we can, in all probability, effect a cure by relieving the condition. I shall, therefore, curette the uterus, dilate the canal and straighten the axis of the uterus by the dilatation and by packing with iodoform gauze. I do not believe that anteflexion alone will cause pain, for I have seen many marked cases of anteflexion without dysmenorrhœa, but anteflexion, by increasing the congestion of the uterus, may indirectly increase the dysmenorrhœa. The real cause of the dysmenorrhœa is an endometritis, and this may be aggravated by the congestion. Forcible dilatation and packing of the uterus will merely change its position. While the anteflexion will not be entirely cured by these means, the sharp angle will be removed and this source of pain will be obviated, while, indirectly, the endometritis will be benefited. You will remember that last week I curetted a uterus on account of granulations with excessive menorrhagia—an entirely different condition from the mild endometritis here present.

The hymen prevents the introduction of the large blade of the speculum. It will stretch, however, sufficiently to admit the small blade, so that there is no need of rupturing it. With a little traction on the forceps I can pull the cervix into view. On attempting to pass the uterine sound I came up against a distinct constriction, but by bending and working the sound I get it through the constriction. The grating of the instrument over the rough endometrium can be felt distinctly, and if the patient were not under the influence of ether she would suffer greatly from this manœuver. The dilatation of the uterine canal is begun with Palmer's instrument which is not very powerful because the ends bend and, as you see, they have slipped out. I next introduce Goodell's powerful dilator. There is a graduated scale to indicate the degree of dilatation, but it is on the wrong side of the instrument for our convenience since, by the inventor, Simm's speculum and the Simm's position are rarely used, the patient being placed in the lithotomy position and the cervix exposed by means of a short bivalve speculum. I dilate the cervical canal gradually to the extent of $1\frac{1}{4}$ inches in order to introduce Holt's cervical speculum. The contractile force of the cervix is still so great that the speculum is forced out, and along with it a large quantity of jelly-like mucous, which is proof positive of cervical endometritis. I have now reintroduced Holt's speculum and, through it, the

uterus is washed out with a bichloride solution. In using Simm's position it is important to have the upper knee slightly in advance of the lower one so that there will be a space for the water to run down without wetting the patient's garments. The uterus is now curetted, sponged out with absorbent cotton and then packed with iodoform gauze, the cervical speculum being used to facilitate the passing of the gauze into the uterus. The gauze will be left in place four or five days unless it comes out spontaneously, sooner.

OVARIAN CYST.

Here is a small ovarian cyst which I found, buried in a mass of adhesions, deep down on the right side of the pelvis. I found a line of cleavage in the adhesions and, as they were not very dense, I succeeded in passing my fingers under the tumor and in gradually enucleating it. On pulling the tumor out of the abdomen I found that the pedicle was small. There was no bleeding of any account and I inserted no drainage tube. From some unaccountable cause the patient developed a high temperature, 104.5°, but the pulse never rose above 110 and, as the patient was of a very nervous temperament, I did not feel much alarm. The temperature remained high for three days and then dropped to normal. Strangely enough the patient referred her pain to the side opposite that of the tumor.

UTERINE FIBROID.

Here is a large fibroid tumor which was removed a few days ago by supra-vaginal hysterectomy. You can see the cavity of the uterus at the plane of section at just about the internal os. The diagnosis was properly made, the woman was suffering so much that she was willing to run almost any risk to get well. The pedicle was secured by the clamp. The patient is doing well, having had only a slight rise of temperature.

MULTILOCULAR OVARIAN CYST.

This is an ovarian tumor whose exact nature I was unable to diagnose. It proves to be a multilocular cyst, but even now, putting my fingers first on it and then on the soft uterine fibroid, I can distinguish no difference in the sensation. The moment that I saw the tumor through the abdominal incision I could tell by its bluish color, that I had to deal with an ovarian cyst, the fibroids being of a dark color and congested. I was obliged to make a rather large incision in order to get the tumor out, otherwise the operation was a simple one. One of the little cysts had burst in the abdomen and some mucoid material had escaped into the peritoneum, causing a slight local peritonitis. The only way in which I could remove the tumor was to open it and clear out some of its contents, thus diminishing its size sufficiently to render its passage through the abdominal wound possible. The fibroid weighed four pounds and a half; this cyst about ten pounds with the fluid. The patient is doing well.

OVARIAN CYST, UTERINE RETROVERSION.

There is nothing especially interesting with regard to this specimen in itself. It is simply an ovarian cyst of considerable size. There were four adhesions in front; the growth had been rapid, dating back only eight months. The pedicle was at least six inches broad but very thin, so that there was no difficulty in disposing of it. The interest centers in the condition of the uterus, which, at the first vaginal examination, was found pressed down by the weight of the tumor into a state of retroversion. The diagnosis was verified at the time of operation and, after removing the cyst, it was found that the round ligaments had become stretched so much that there was no effort on their part to hold the uterus up in place. To have sewed up the abdomen with the uterus in that retroverted position would have caused needless suffering, especially if the uterus were to be kept functionally active by the presence of an ovary. In this instance I removed both ovaries, but whether that is done or not, I think it is the duty of every operator, after removing a tumor from the pelvis, to carefully examine the position of the uterus, and to correct it, if such correction be necessary, before he closes the abdomen. For I believe that even after the removal of the ovaries a retroversion may cause trouble. On this point I insist most strenuously. Young operators especially are too apt to be content with the completion of the originally planned operation, and to leave the correction of such a comparatively small matter as a displacement unattended to. This is all wrong. We should leave nothing undone which may count for the

future welfare of the patient. All the pelvic organs, the whole abdominal cavity in fact, should be carefully explored, and any pathological condition which may be found, corrected at the time, provided it is amenable to surgical treatment.

Now, in this case, I found that by pulling on the round ligaments I could bring the uterus into proper position; hence the indication for relief was clear. The first operation for shortening the round ligaments was brought into notice by Alexander, of Liverpool, and is generally known by his name. I attempted this operation very soon after its introduction into this country. At first I failed to find the round ligaments. But, after careful dissection on the cadaver, I met with no trouble; especially after I had adopted the plan of opening the inguinal canal and seeking the ligaments within its borders. Still my experience with Alexander's operation has not been happy. After finding the ligaments I have several times discovered them to be adherent, or too weak to bear pulling out. The patients have also, in several instances, experienced great pain and "pulling" in the scar afterwards, so that their last state has been as bad as the first.

From these experiences, and from the fact that Alexander's operation takes no account of any possible co-existing disease of the uterine appendages, I have almost entirely given it up. The number of my cases have not been large, and I would not like others to draw too positive inference from my experience. I am myself open to conviction in the matter, and am willing to take it up again if I see good reasons for so doing, and especially if the element of doubt can be removed from the result. I have, however, yet to see the operator who does not sometimes meet with failures, and only recently an acquaintance told me that he had seen five failures in the Women's Hospital, of New York, from this operation.

It is certainly not a desirable operation when we have the abdomen open and the round ligaments accessible. There are three or four different plans of shortening the ligaments under these circumstances. We may lap the ligament on itself and take a couple of stitches so as to hold the folds together. Inflammation and consequent adhesion of the peritoneal surfaces of the ligaments will bind the folds together. I prefer silk sutures as being more permanent. This is Wylie's operation. Polk's operation consists in doubling in both round ligaments just in front of their attachment to the uterus and sewing the two loops together. If, at the same time, the loops are sewed to the fundus uteri by a stitch running under each ligament and through uterine tissue (Dudley's operation) the attachment of the ligaments is made to a higher point of the uterus where they have a mechanical advantage in overcoming the tendency to posterior displacement. In this case there was a little fibroid tumor the size of a marrow-fat pea in just the right spot for the attachment of the ligaments. I removed the fibroid, controlled the hemorrhage by pressure and stitched the ligaments to the uterus at this place. There was still a little oozing which I controlled with persulphate of iron, for any exudation in front of the uterus would require a separate drainage-tube from that placed in Douglas' cul-de-sac, and I did not want to put in two tubes. There was considerable oozing from the abdominal wound, so that it was necessary to insert a posterior drainage-tube, but this was removed after twenty hours.

Even if you do not do laparotomies yourself these points will be of service to you. The specialist to whom you take your cases may be one who does not pay much attention to displacements, and it would be perfectly proper for you to insist that at the time of operation he should correct the displacement of the uterus. The correction of the displacement does not complicate matters at all at the time of the operation and it adds greatly to the chance of perfect recovery later. I am treating cases at this very day which, I believe, would have recovered completely had I corrected the uterine displacement at the time when an ovarian tumor was removed. Text-books have not yet begun to insist on this point, but I have called attention to it several times in the last two or three years. The time is past when we simply looked out for the life of a patient at a laparotomy. Good operators lose not more than four or five per cent. of all kinds of cases. We must have in mind the entire future welfare of the patient and do everything at the time of operation that will exert a favorable influence on the general health of the woman.

COMMUNICATIONS.

HYDROPHOBIA.*

R. P. TALLEY, M. D., Temple, Texas.

I feel reasonably certain that what I have to say on this occasion will, to some extent, antagonize the views of a large majority of the medical profession and, therefore, I shall expect criticism; but this is the common lot of all searchers after truth, and just in proportion as the investigations of these searchers after truth or facts tend to upset popular fallacies, so in that ratio is the criticism of their efforts liable to be more or less unjust. I know of no more difficult or thankless job for the truth-seeker or man of science than to endeavor to upset a popular fallacy. Most persons say in the language of Shakespeare:

> "Until I know this sure certainty,
> I'll entertain the favored fallacy."

My sole object is to work in the interest of truth. Notwithstanding the much lauded words of Lord Justice Knight Bruce, that "Truth, like all other good things, may be loved unwisely, may be pursued too keenly and cost too much;" I say, let us get the truth and the facts in all matters coming under our investigation, cost what they may. I have no higher God to serve than truth, and no lower and baser hell to fear than falsehood.

Hydrophobia is generally used by the profession and the laity to indicate a disease, when in fact it is only one of the symptoms of a supposed disease. Dunglinson says, "The term rabies is more appropriate for the aggregate of symptoms resulting from the bite of rabid animals. Hydrophobia literally signifies a dread of water; and, consequently, ought to be applied to one of the symptoms of rabies rather than to the disease itself." I, therefore, prefer to use the term rabies in this discussion.

At the very threshold I assert that there is not now, nor ever has been, any such disease as rabies outlined and defined with any certain and definite symptomatology. I have not found a line in any of the medical literature to which I have had access during the past thirty years, by which I could certainly and definitely identify any morbid condition as rabies. This name was born with the very beginning of medical literature, but neither the medical profession nor the laity have been able to identify the disease bearing the name, beyond all doubt. It is an illustration of how unfortunate it is "to name the child before it is born." We have the name, rabies, but where is the disease? Compare the symptoms, the evidence required thirty or forty years ago to make out a case of rabies with what is required now, and you will find there is no substantial agreement.

If rabies ever existed it does now, and conversely, if it does not now it never did. True disease, a disease entitled to the dignity of a name, must represent some unvarying morbid change in some element of the physical or mental organization. For example, diphtheria, small pox, etc., were the same in the seventeenth century as to-day; they are recognized by the same symptoms now as then, and these symptoms depend upon certain recognized, stable, morbid processes. But upon what stable, recognized or certain symptoms can we determine the existence of rabies? I insist that the evidence to identify rabies in court, either physical or rational, is all along the line simply negative. If there is any positive testimony, where and what is it?

In seeking to find out some definite way to diagnose this so-called disease, it is sickening and discouraging to read the great and numerous contradictions found in its clinical history, as given in medical literature by the best writers of the past and present time. If those who take a different view of this subject will, unbiased, read this literature, I think they will at least conclude with Dr. Brill, of New York, that the existence of the disease called rabies has not yet been proven. After referring to cases clinically reported forty years ago as

*Read before the Central Texas Medical Association, January 10, 1893.

well as at the present time, he says: "These cases are sufficient to show the variable character of the clinical histories, and serve to uphold the statement, which I have elsewhere made, that no two cases of this alleged infectious disease are alike; also that the symptoms of rabies considered to be characteristic of the disease by the earlier writers are not mentioned as such by those of the present day. Its alleged etiology shows as great discrepancy and absurd statements as could possibly be mentioned." A little farther on he says: "The animal, some claim, need not be rabid to produce the disease. Others deny this statement; some assert that the disease can originate in the animals named, (meaning the canidæ, mustelidæ and felidæ), *de novo*; others deny this absolutely and ridicule such a belief." He then says: "We deny to-day, as we denied some years ago, that there is any specific infection from the bite, or, that the existence of the disease in the dog has been sufficiently well established."

I admit, because it is a physical tangible fact, that disease and death result from the bite of dogs, mad from any cause. But, I contend, that it has not been proven in any logical or otherwise satisfactory way, that the cause of this so-called disease is from any specific infectious poison of invariable qualities, introduced into the system by the bite of a dog. In my judgment rabies is a hypothetical disease for which the whole world has been trying for centuries, and trying unsuccessfully, to establish an entity. Where, I ask, is the microbe of rabies? I have not heard that it has been identified in any court of competent pathologists! And, where is Pasteur and his treatment of rabies to-day? I have not read anything from him for some months, but not a great while ago, he was still as usual changing his views on the subject and swearing by the last as the only treatment. If he keeps jumping it will be difficult to overtake, much less keep up with him. However, I have a good word and a warm place in my heart for Pasteur. Perhaps he has demonstrated that, pathologically speaking, there is no such disease as rabies, and, therefore for this, if for nothing else, humanity owes him a debt of gratitude.

It is my opinion now that all deaths in animals such as the dog, wolf, cat, etc., from the so-called rabies, could be more satisfactorily accounted for by diseases and injuries well-known, and explained by proper pathological and physiological investigation, without wasting time trying to make an entity for rabies. It is an indisputable fact that whenever a domestic animal, as the dog is sick so as to lose his common sense, the laity, and far too many doctors, at once say it is *mad*—has hydrophobia, and can be killed none too quickly. Then and then only follows the great and most serious cause of trouble for human beings, and this is *panic*. This panic is not confined to the patient himself, but it extends to all of his associates as well. It grows in seriousness and intensity with each day. There is no one to even attempt to allay it. Well-meaning but misguided friends tell of all the horrible deaths from rabies of which they have ever read or heard; the doctor looks wise, as usual, and it may be sympathetic, and, in as kind and loving manner as possible tells the patient, his relatives and friends that there is no cure for it, that it always ends in death of the most painful and excruciating character and that it may come at any time in from 9 days to 9 or 100 years! Given the same panicky surroundings, would not any other disease prove equally and as certainly fatal? While it is a fact that the most fearful suffering and death follow the bite of certain animals, whether mad or not, yet, n my judgment, there is no disease *ab initio* entitled to the name of rabies, *except* this form of panic. This panic may destroy life, as has been proven many times, negatively at least, by post-mortem examinations without any sort of anatomical lesions. This is freely admitted by the most enthusiastic advocates of the disease called rabies.

Only a short time ago I received from the author, Dr. Arthur E. Spohn, of Corpus Christi, Texas, an article on "Rabies and Anti-Rabic Inoculations." I need hardly say he is an enthusiastic advocate of the disease and Mr. Pasteur's cure. He says: "The disease is generally described as having three stages: Melancholy, irritation and paralysis.

Each stage has its peculiar symptoms. A person is bitten by a rabid animal; before the period of incubation of from 16 to 199 days has passed, if the patient is very nervous, we are liable to have emotional symptoms, or spurious rabies,

where the symptoms will simulate all accounts of hydrophobia he (the patient) ever read or heard of. I have known them to have attacks of intense melancholy commencing within a few hours of the injury. I believe many persons die from spurious rabies and, while in no way depending on a specific virus, if continued will run into melancholy, irritation and death. It is in such cases, and they are far the most frequent, where properly directed treatment will have a beneficial effect; while for the true rabies there is at present no known remedy, our only hope is in prevention.

"This period of incubation, or latent period, lasts from 16 to 199 days, an average of 48.73, which corresponds with the period given by Mr. Youatt of from 42 to 49 days. During this latent period the wound generally heals; the person returns to his ordinary avocation, still is not free from suffering, often becoming extremely nervous, restless and excitable—living in constant dread of the approaching results. It is this state of uncertainty which makes rabies such a terrible affection. On many occasions I have been consulted by persons months and even years after they had been bitten by supposed rabid animals, telling me that their lives were completely useless; living in constant dread of the horrible results. One man who was under my observation had been bitten by a wolf. For about a year and a half he suffered intensely, was not able to attend to business and died of paralysis. I have no doubt this man died from the result of the injury."

It will be observed that Dr. Spohn says there are two kinds of rabies, the real and the spurious, of which the latter is far more numerous. It will be further observed that he says the maximum time for incubation is 199 days, yet this man's death occurred 547½ days after he was bitten. The doctor says he has "no doubt this man died from the result of the injury," nor have I the least doubt of it, but it was 547½ days of panic which killed him not rabies. This was the anatomical injury, the pathological condition which caused his death.

Dr. E. C. Spitzka, of New York, who is an educated gentleman, and one who has had large experience in veterinary medicine, says he has never seen a case of true hydrophobia. In writing upon "How We Can Prevent False Hydrophobia," he quotes the following from Pepper's System of Medicine by American Authors, the particular author quoted being a believer in the reality of hydrophobia. The quotation refers to cases of more than usual interest and I offer no apology for giving it at length.

"The langor and nervousness attendant in extreme heat tend not only to hasten the activity of any disease germs actually present in the system, but also strongly favor the increase of that nervous fear which so often generates a fatal psuedo-hydrophobia (lyssophobia) in persons that have been bitten by dogs.

The most difficult to distinguish from the general disease are those cases in which hydrophobia occurs as a disease of the imagination, the result of fear, the lyssophobia of the writers. In these there is always the history of a bite, the cicatrix even may have become the seat of congestion, redness, itching, or neuralgic pains and these, acting on a susceptible brain, develop a disease which is hardly distinguishable from true hydrophobia and which is quite as fatal if left to run it course. These cases have usually less reflex susceptibility than genuine hydrophobia; the attack mostly occurs shortly after some conversation on the subject, and especially about the effects of the bites on others, and the victim is seen to have been subject to hysteria or other nervous disorders. *At the same time the concentration of the mind on this subject sometimes produces even structural changes in the medulla*, and the reflex susceptibility in coördination with the other symptoms may be almost perfect. In a case reported a few years ago by Hammond, the symptoms appeared perfectly characteristic, and at the necropsy circumscribed points of congestion were found near the roots of the vagus; yet the dog that bit this man was said to be alive and well, and, in the absence of any successful inoculation from biter or bitten, the case must be presumed to have been lyssophobic.

Many cases with a more favorable issue are recorded. Bellenger had a patient who had been bitten by his cat and manifested violent paroxysms of hydrophobia, but was instantly cured by the sight of the animal in good health. Browndel records the case of a man that was bitten by his dog, which

afterwards disappeared. He was seized with severe hydrophobia which continued for two days; when the lost dog was found and presented to him the symptoms disappeared. Trousseau speaks of a magistrate whose hand had been bitten by his hound, which immediately after attacked a flock of sheep, so that many of them died from rabies. The master then manifested hydrophobia, but, as death was deferred beyond the usual time, he concluded it was not genuine and recovered. Professor Dick was called to visit a man who had been bitten by a favorite dog, which, while suffering from distemper, had manifested severe hydrophobic symptoms, and had been given up by the attending physicians. He succeeded in convincing the subject that as the dog had had distemper and as no two great diseases could exist in the same system, it could not have had rabies. In spite of the false premises this reasoning had the desired effect and the patient recovered. A few years ago a boy, 12 years old, in Ithaca, N. Y., was bitten by a dog supposed to be rabid and, in due time manifested hydrophobia, which advanced rapidly until he was having a violent paroxysm every half hour, and it was pronounced impossible for him to survive another day. At this time I saw him, observed that he had a nervous organization and was somewhat lacking in the hyperæsthesia of rabies. I learned that he had recently been gorging himself with Christmas delicacies and was very costive, and as there was no satisfactory history of the dog, I at once suspected lyssophobia. The friends and strangers who had come to condole with the parents and feast on the horror were excluded, and the boy's attention fully engaged in amusing pictures and conversation. The paroxysms were omitted and, in two hours, the patient overcome by weariness, went to sleep. Next morning he was still kept secluded and quiet, and two enthusiastic students took up the role of keeping his attention constantly engaged on whatever would interest him. The *prima via* was relieved by medicine, and under a course of tonics he quickly recruited, and at the end of the week went back to school."

Dr. Spitzka also relates the following: "A case occurred in this city a few weeks ago, which illustrates how a little good sense on the part of a physician may avert a calamity in the same manner so happily effected by Professor Law. A boy of 13, had harnessed his own and another large dog to a boy's cart. The reins got entangled and the dogs quarrelled. The boy went to the assistance of his own dog and was snapped by the antagonist. He thought little of it; but the boys on the street told him he was doomed to die of hydrophobia. Some grown-up imbeciles—not inmates of a lunatic asylum, but fellow citizens entitled to vote—joined in this verdict, and the poor boy came home with his face as white as chalk, kissed his mother good bye and, saying he had to die, disposed of his little possession. The family physician was called in about 8 o'clock. Instead of pooh-poohing the matter which, though practicable, would not have effected his purpose so well, he said: 'Well, my boy, I see how it is, you are passing through a crisis. If you survive 9 o'clock this evening you are positively safe." The child's attention was thus fixed upon the minute hand of the clock; after it had passed the critical point no more hydrophobia was heard of in *that* house."

Cases of the kind above described have induced the advocates of rabies to divide it into two kinds, true and false, or hydrophobia and lyssophobia. The only real distinctive features between the two being these: if the patient dies it is true hydrophobia, but if, by any means, the panic to the mind is allayed and the patient recovers, then it is beyond all doubt or question lyssophobia. All this seems to prove and confirm the assertion I made in the beginning that the disease is altogether the result of panic. I do not believe there is a well-established case on record, of the death of anyone from this so-called disease, where the mind of the patient has been fully and entirely relieved from the intense strain and pressure it always undergoes in such cases. See how many are cured, as they call it, by the application of mad stones. Scientific men know there is no intrinsic virtue in them, yet they allay the panic in the mind, and thus afford relief. Anything else affording relief to the mind would answer the same purpose.

I believe it is Green who, in his work on pathology, says: "If the habit and thought of the medical minds were more analytical and, if physicians would reason and draw conclusions logically, governing

their deductions by strict logical law, many changes would be made in the now accepted opinions of etiology and pathology." Let us endeavor to follow his advice. Let us seek truth for its own sake, and when we find it let us open the doors of our minds and receive it no matter how many old theories and popular fallacies it may drive out. In the language of the Bible, let us prove all things and "hold fast to that which is good."

It will be observed that the most zealous supporters of the theory of hydrophobia admit that people have suffered and died from false hydrophobia, and it is also admitted that a large majority of the cases are of this kind. Hence, it follows that the people have been so educated, and improperly educated that, before this so-called and pretended disease, they become panic stricken and die most terrible and excruciating deaths. Remove the great fear, the intense dread; in short, prevent or, at least, allay the panic and the disease will disappear like dew before the morning sun. The medical profession has contributed largely to the false education of the people on this subject. This being the case, is it not incumbent on us to use our best endeavors to correct this great, serious and fatal error? If we have in the past in any way contributed towards educating the people so that they become panic stricken and die, is it not our duty to now use our best endeavors to restore their calm reason; remove the panic, in short, educate them to live?

THE PRESENT STATUS OF URETHRAL SURGERY.

E. R. PALMER, M. D., Louisville, Ky.

Otis published his first case of successful urethrotomy with the Otis instrument, in the *New York Medical Journal* in 1878, and it may be safely said that in about the year 1883 the craze of promiscuous internal urethrotomy struck this country. That Otis has done much good work, and has contributed some valuable and vital information to genito-urinary surgeons is beyond peradventure, but that the operation has been very much misused, and very much abused, and very widely and unwisely applied is also beyond peradventure. In June, 1890, I reported fourteen cases of successful internal urethrotomy for close stricture at the bulbo-membraneous junction, without perineal section. When Otis went abroad early in 1880, and advocated his operation on the principle that all gleet was dependent upon stricture, that all stricture could be cured by internal urethrotomy, I may say that the foreign surgeons almost without exception, opposed his doctrine; and notably the English, among them Mr. Harrison, who declared it was an unsafe, dangerous and unsurgical procedure to cut stricture of small calibre by internal urethrotomy, without at the same time making a counter opening in the perineum so as to permit the escape of urine, and to prevent the danger of hemorrhage into the bladder.

As before stated, in 1890 I reported fourteen cases of urethrotomy for close stricture of the bulbo-membraneous juncture without external urethrotomy, without a single complication and with a permanent curative history. At the meeting of the State Society in June last, I reported twenty additional cases, unselected, of the same operation, with the same history. I have here copied from my case book for 1892, a list of fourteen more cases of operation for close stricture, in men who could not urinate except with the greatest difficulty, and in some cases could not urinate at all, where the catheter even could not be passed. Fourteen additional cases of urethrotomy without external urethrotomy, and in these fourteen a history of complete cure in every case.

At the meeting at Altoona, the opinion of nearly every one present was to the effect that Harrison's operation, namely, the operation through the perineum, should be done jointly with internal urethrotomy. Last June at the meeting in Richfield Springs, New York, Dr. Taylor made the

*Read before Medico-Chirurgical Society, Louisville, Jan. 20, 1893.

statement that he was entirely in accord with me in the belief that the operation for close stricture in the urethra could be safely done without perineal section, with as much assurance of permanent curative result, as if the operation advocated by Harrison, viz: the opening of the perineum into the membraneous urethra—was done at the same time as the operation for internal stricture. So that I feel—with a report now of something in the neighborhood of fifty cases without a solitary case of hemorrhage into the bladder, without a solitary case of complication of any sort, and these unselected cases running anywhere from twenty-one to seventy-four years of age—that I am safe in claiming that there is no necessity for opening the perineum when it becomes evident to the surgeon that it is necessary to do an operation for close stricture of the urethra.

The most important thing about operations for stricture of the urethra is the proper classification of cases. It goes without saying that there are men here to-night who would continue to discuss until daylight as to the most desirable mode of treating urethral stricture, as between dilatation, or divulsion, or section by the knife. Beyond any question a great many surgeons have very unwisely cut the urethras of men suffering with stricture, and beyond all question one of the results of unwise cutting of the urethra for stricture is impotence and a more or less permanent deformity of the penis during erection. Beyond any question the operation is being done too often and very unwisely by men who claim that all cases of unsymmetrical urethra or of gleet should receive the knife. I think it has never been emphasized as it should be, that the law of inverse ratio is nowhere more positively exemplified than it is in urethral stricture, namely that the worse the stricture the better the result. When I first began working in the matter of urethral stricture I cut nearly everything where there was any contraction or any irregularities that the bougie a boule would detect. I did not believe there was much virtue in the treatment by sound for permanent cure of stricture. Since then however I have changed my practice and never cut a stricture until it has been demonstrated that it cannot be cured by dilatation, or until it has become an extreme case of close stricture. I now seldom cut a stricture of large calibre, but do cut all close calibre strictures and, as before stated, the worse the case the more certain and permanent the good result. Before showing one or two instruments I want to emphasize what I have just said by reporting two or three cases.

No. 1.—Bank clerk, came to me with impotence, with the statement that he had never had a proper erection in his life; that he had been under medicine, and under urging in the way of becoming self confident, etc., attempted to demonstrate to himself his manhood. He had completely failed in this, and stated that he absolutely never had any venereal connection with any woman; that he had an abundance of opportunities in this direction, but had never been able to have a normal erection. I made an examination of his urethra, and about 1½ inches back I found a stricture that almost completely obstructed the passage. I was able after repeated attempts to introduce a very small bougie. After making a careful examination, I made the diagnosis of mechanical obstruction that I believed prevented the inflation of the blood vessels or the glans, and while I was not convinced that it was a stricture properly speaking, still I believed that there might be a cure in this case by the splitting of this obstruction. So I, with much difficulty, passed an Otis instrument, believing that the necessity of the case demanded it. After splitting the obstruction freely, I was able to pass a No. 32 curved sound without any difficulty, and afterward passed a No. 32 straight sound. This operation was done three or four months ago, and he reports to me now that he can not only command an erection, but has also had satisfactory sexual congress. He is a very intelligent, rather intellectual, well developed young man, who has reached his twenty-sixth or twenty-eighth year, and had this trouble, which was probably due not to stricture, but to a neoplasm in the urethra. Of course the question of removing it by other means as a better surgical procedure, is one of considerable importance.

No. 2.—Some time ago a man came to me from an interior town, with a perineal fistula the result of a perineal operation for stricture of the urethra. The stricture which still existed, was promptlycut with

the Otis instrument, and as there was considerable shock following the operation, I gave the patient a drink of whiskey; he said to me "Doctor, you do not realize what you have done," and I replied that I realized I had cured him of a very serious trouble, as I believed that the fistula would close. He then remarked that he never took one drink of liquor without getting on a big spree. I told him that he would not get on a spree in this instance, and to be sure that he did not I took him to the train and saw him safely off toward home. He stopped at Lexington and went on a drunk for about a month; however the fistula closed and I understand he became entirely well.

No. 3.—Another case almost parallel with this as regards the nature of the stricture, was one that Drs. Roberts, Yandell and Rodman had been dilating for a year and perhaps more. The stricture could be dilated up to a 32 sound, and then in a very short time would contract again so close that it was almost absolutely impermeable. In this case the cutting operation was done without perineal section, and the man got well without any unfavorable symptoms at all.

No. 4.—The next case was one that Dr. Roberts also saw. A man who had a close stricture at about the bulbo-membraneous juncture, was taken down with a violent fever, and after recovering from the fever had a perineal abscess resulting in a permanent perineal fistula which some doctor in Indiana operated to close. When the patient came to me the perineum was gaping widely with some of the stitches still in situ. Two well marked strictures were found in the urethra, which were promply cut, and the fistula closed, the patient getting entirely well without further operation.

No. 5.—A fire insurance man, aged 74 years, came to me stating that he had had stricture of the urethra for over fifty years. A prominent homeopathic physician in the city told him that he had an enlarged prostate. An examination showed that he had a perfectly normal prostate, but had eight strictures of the urethra, one right back of the other. A careful examination of the urine revealed no disease of the kidneys, and no abnormal condition except the strictures. The patient had to rise frequently during the night, urinating at all times with extreme difficulty. The operation of urethrotomy was done without perineal section, and the man is now perfectly well. He is entirely cured with the exception that his expelling powers are not as great as they would be were he a younger man.

In regard to hemorrhage into the bladder in these cases, Keyes states if you have a clot in the bladder do not interfere with it. If there has been a clot in the bladder, or hemorrhage backward in any of the cases I have operated upon, I am not aware of it. I have simply reported these cases to prove, or to emphasize my firm belief that it is not necessary to put patients of this character in bed for two or three weeks, as will be the case if you open the perineum.

Now in the rapid progress of urethral surgery comes the question of the urethroscope. As the elder Otis was a firm advocate of the doctrine that all gleet was dependent upon stricture and all stricture called for the knife, so the younger Otis comes to the front with the most perfect urethroscope that has ever been devised. By means of it we are enabled to explore the urethral canal, and definitely locate any stricture or neoplasm, or any other conditions which may exist, that cannot be cured simply by internal urethrotomy. We all know what the experience has been in Louisville with the cystoscope; it has been previously expressed in this society that it is not the most reliable instrument in the world. I think, however, that the urethroscope will come into quite general use; without mentioning any names I may say that three or four of the prominent young men in this city, have been recently entirely cured of persistent urethral trouble by its means. By its use the exact location of the ulcer or inflammation can be determined, and the proper solution can be applied directly to that point. I think this fully demonstrates the fact that the improved Otis instrument is of value, not only in stricture, but in other conditions which we find in the urethra equally as serious as stricture.

She—Professor, did you ever read Martin Luther's commentary on the "Diet of Worms?"

The Professor—No, I have not. I am a strict vegetarian, you known.

SOCIETY REPORTS.

THE MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, January 20th, 1893.

THE PRESIDENT, Dr. F. C. Simpson, in the Chair.

OVARIAN TUMOR.

DR. A. M. VANCE: The specimen I exhibit here is an ovarian polycyst and the other ovary removed from a maiden lady forty-two years old. The only point of interest is that her attention was never called to the tumor. It was discovered by her physician who was called on account of some pain during menstruation. The tumor contained a number of cysts and the cystic fluid was very thick. The whole operation was done in eighteen minutes.

BUBO.

DR. W. O. ROBERTS: Two years ago I saw a young man with a chancroid on the penis, which was followed by a bubo in the right groin, which, of course, went on to suppuration and was lanced. There was no further trouble until two weeks ago. Then he came to my office with an enlargement in the groin, which he said came on after pretty hard work at the store, in which he had done some heavy lifting; that he had felt some pain in the groin and that in a short time it began to swell. When he came to my office the enlargement was about the size of the first joint of my thumb, and quite tender. I put on a compress and bandage which he wore for ten days; but instead of improving the swelling continued to increase and, finally, I made a free incision into it and a considerable amount of pus escaped. The incision was very long—over two inches, and the suppuration seemed to be from around the gland instead of from the gland itself. I then put on an antiseptic poultice and bandage, continuing this treatment for three or four days; the gland seemed to increase in size and all the time the suppuration continued to come from around it, and I thought possibly I had not gotten into the gland. I then held it with a pair of forceps and cut through the centre, but no pus came away. I then put the patient under chloroform and removed the entire gland. I exhibit it here for your inspection; it is now very much shrunken from being in alcohol; it was dissected out with my fingers, leaving a very large cavity.

DISCUSSION.

DR. E. R. PALMER: I have read, in the last few days, a paper from one who wrote as if he thought he had discovered the only way to treat bubo with all its complications; and the only point he makes of any particular value, is that peri-adenitis is often antecedent to suppuration of the gland itself; and he advocates, instead of early opening, the very latest opening possible in order to allow of full destruction not only of the gland but of the connective tissue about it. And then he favors the trimming off, under chloroform, of the entire roof. This is the old operation and leaves a broad, wide and open ulcer which you can curette, clean and pack, treating so that it will be sure to granulate from the bottom, resulting as he says in a smooth and almost normal cicatrix.

We were promised a year ago by Dr. Francis Watson, of Boston, a paper on the treatment of bubo based upon his statements that the ideal treatment had never yet been formulated. But unfortunately he went abroad and the paper has never been read. And I must say, when it comes to making these enormous openings with a view to radical and speedy cure, that you leave the patient in such condition as will certainly cause him, throughout his entire after life, to conceal his person lest the exposure of this broad flat or depressed cicatrix will tell the story of his previous infection. I think it is a big question in treating these inguinal abscesses in young men, whether we shall give them a speedy cure by radical and rapid surgery that shall clean out everything, making a wide open sore, and leave them with a broad mark that will remain with them through life, or whether we should prolong the treatment for a few weeks, or perhaps several months, and finally get them well

with only the merest white line to mark the place where incision was made, the skin not having been removed, thus insuring in later life the precaution against exposure that may come. In treating young men for suppurating groins, we are bound to recognize a fact which we all know as doctors in middle life, that it is very important to have a man so that in later life he can throw off his clothes or go to sleep on a hot summer day with the possibility of his shirt getting above his groins, without exposing a great, broad, depressed cicatrix such as comes from these extensive operations. In my own work I am not afraid to do radical operations in the groins, and am perfectly willing to do them, but when a young man presents to me with glands of this sort, I nearly always procrastinate and work through small apertures, curetting through them, using peroxide and bichloride of mercury solutions, doing a great amount of hard, tedious work, extending over quite a period of time, with the simple idea that a few weeks or even a few months are nothing to a man if, in the end, he can be cured with such treatment and be in a presentable condition later on in life. Every married man, who has lived up to middle life, knows that a man is liable in his bath and in his domestic life to expose himself very generally, and I have seen cases where these glands were taken out, leaving a large scar which might have been avoided by proper treatment. Every one knows that by radical treatment in these cases, we are apt to get these big scars, and what is the best surgery from a purely surgical standpoint has not yet been fully determined to be the best practice. I am speaking largely not only with reference to the operation as performed by Dr. Roberts, but with reference to Dr. Rodman, both of whom operate extensively on the groin, and also with reference to the article which appeared in the journal mentioned. This man's idea is to simply first open and evacuate, then at the last moment making a large incision and with scissors trim off and take out the entire roof and make a large open sore that can be curetted, cleaned, disinfected and treated, with a resulting cicatrix which comes, of course, in a short period of time; this usually leaves a pale, hairless, depressed cicatrix which we ought to try and avoid in young men who have thirty or forty years of married life coming to them afterward.

Dr. C. Skinner: What per cent. of bubœs suppurate in your experience?

Dr. E. R. Palmer: Syphilitic bubo almost never suppurates; gonorrhœal do sometimes and virulent bubœs always. I have had patients where there was a patch as large as a dollar, of blue tissue which could be lifted up, and that you could get under with your curette or with your probe. Under this treatment advocated by the writer in the journal referred to, the operator would take a pair of scissors and trim off this entire flap with the view of getting an exposed ulcer which can be cleansed, disinfected and curetted. His idea being that the under surface of this diseased skin is filled with material that contains the bacteria of suppuration, which will keep infecting the tissues underneath. But I believe that this flap can be cleansed, and better results and less scar obtained by not trimming off the roof. By reversing your curette you can clean the entire under surface of the skin. I have done this in several instances until the skin was as thin almost as linen cloth. You can curette in this way and then cleanse by frequent washes of peroxide of hydrogen, followed with bichloride of mercury, then by a carefully adjusted compress with spica bandage, you can preserve this piece of skin and the wound will heal leaving only a very small cicatrix which cannot be discovered without close inspection. So far as the surgical treatment is concerned, it is a very easy matter to make a counter-opening, if necessary, and insert a drainage tube. I have sometimes found it necessary to do this. Frequently in cases that have previously had suppurating bubo, you will find ridges of considerable size left. It has been my experience that these ridges under constitutional treatment, under cod liver oil, under hydriodic acid and under a properly adjusted compress, can be gotten rid of. I believe that the treatment of this condition is a question that will be very largely discussed in the future.

Dr. A. M. Vance: Do you mean this talk to apply to glands where suppuration has already occurred before being seen by you?

Dr. E. R. Palmer: Yes, of course. I see comparatively few suppurating glands. It is perhaps remarkable that I see so few of them. A great many of the cases that apply to me have passed through the hands of other men.

Dr. A. M. Vance: In cases of chancroidal bubo without suppuration, do you practice prophylactic treatment of the gland?

Dr. E. R. Palmer: In chancroidal bubo I do not believe with the extirpation of the gland you can hope to remove all the infection. I believe that the lymphatics are involved to such extent that the enucleation of one enlarged gland will hardly remove the source of infection. In addition to the enlarged and infected gland there is, in nearly all cases, a peri-adenitis below and around the gland itself.

Dr. W. L. Rodman: I take issue entirely with Dr. Palmer as to the question of scarring. I think the bad scars he has seen must have been caused by the very practice he advocates. It is only very recently, and by a few surgeons, that these glands have been dissected out bodily. I think that the operation should be done not only to save time and get the man out as soon as you can, but for the very purpose of preventing scarring. If the operation is carefully done the scar left is so small as to be scarcely noticeable. I recalled three or four cases, while Dr. Palmer was speaking, upon which I have operated for enlarged glands (and I would like to have had the patients here to-night) where the wound was closed by deep as well as superficial sutures, and where union took place by first intention. In one case I found that suppuration had already taken place in the gland; it was carefully dissected out bodily, without infecting the wound which healed by first intention, and today I doubt if a scar could be seen. I operated upon a man at the city hospital, who had enormous glands in the groin, and there was union by first intention in the same way. The resident physician, Dr. Tomlin, operated upon the other side shortly afterward, the wound healing by first intention. In this case I doubt if today you can see a scar on either side. I would operate for the purpose of preventing scarring. The majority of these cases will go on to suppuration, and we cannot prevent scarring if we allow the tissues to break down themselves. If the glands are dissected out carefully and deep sutures inserted, there will be no trouble at all, and you will have no depressed cicatrix as you will have should they discharge spontaneously. I think every gentleman here will agree that where you find enlarged glands on the neck or face, and you are satisfied that they are going to break down, it would be very much better to make a small incision and dissect them out, in order to prevent suppuration and the formation of ugly, depressed cicatrices we so commonly see in patients treated by poultices and other expectant means.

Dr. E. R. Palmer: I suppose all men have curious experiences and, simply to emphasize that, I am going to say that I am treating a very large number of cases of gonorrhœa seven days in the week, and I do not think I can recollect, in eight years' practice, five cases of suppurative glands from gonorrhœa that have opened. I have had some pretty large glands in gonorrhœa that have eventually disappeared. I believe these very glands Dr. Rodman has opened and found pus in, had they been subjected to less radical treatment, would have disappeared.

I have a case under treatment now, a young man who had some femoral glands enlarged from gonorrhœa, that a doctor in the city, one of the regular members of the profession, diagnosticated as rupture and applied a truss for its relief. When the patient came to my office there were two or three openings leading up to a broad extensive sinus; the overlying tissues were very much diseased and blue in color; there was also a counter-opening communicating with this sinus that had been formed by the truss, In this case we removed the truss, dilated and curetted the infected portion of the tissues, injecting peroxide of hydrogen then bichloride of mercury and treated it with antiseptic agents. The patient is doing well, and I think will finally recover without any scar. I do not, in my work, see one case in a thousand where there are suppurating glands from gonorrhœa that need evacuation.

Dr. A. M. Cartledge: What do you consider the pathology of gonorrhœal bubo?

Dr. E. R. Palmer: You know the statement that Bumm made in regard to the child that died—that the cord was invaded by the gonococcus and that the gonorrhœa had followed the cord up. I do not exactly agree with Bumm concerning the pathology. I believe that bubo is caused by the germ of suppuration—at any rate I do not think the gonococcus does it. It must be the pyogenes—must be the pus bacterium that produces it.

Dr. A. M. Cartledge: You believe then, that suppuration which takes place

in the inguinal glands in gonorrhœa, is produced by the pus-forming micro-organisms?

Dr. E. R. Palmer: Yes. I do not think it is always necessary or advisable to open these enlarged glands, but by pressure and careful management you can reduce them without extirpation. I know it is very tempting, and it is a beautiful operation to go down into the groin and dissect out these glands, cleaning them out thoroughly, carefully stitching the wound, and allowing the patient to get out in a comparatively short time, but it has been my experience that, by this treatment, there will be more or less scar left as a result, which could be prevented by the treatment I have suggested. I have seen a great many cases of so-called tuberculous enlarged inguinal glands and believe they should be at first subjected to the same treatment.

I want to stand fairly and squarely as an advocate of conservatism in the treatment of enlarged glands. I have never yet seen a case of enlarged glands from gonorrhœa that needed extirpation.

Dr. C. Skinner: I desire to say that I want to stand just as fairly and squarely on the other side of the fence in regard to the treatment of bubo. I think the only plan is to enucleate these buboes as soon as they show any tendency whatever to suppurate or break down. I have been doing this now for some little time—promptly enucleating the enlarged glands at the first appearance of suppuration.

In regard to the scar, I want to mention one case to show the effect of an operation for removing a scar, and at the same time removing a suppurating gland. Some time ago a young lady came to me with a swelling on her neck, who in childhood had had a suppurating gland of the neck which had been opened leaving a very ugly scar and one so deep that she had great trouble in keeping it clean. This swelling occurred near the old scar. I told her that I believed the only thing to do was to make an incision, removing the suppurating gland and at the same time take away this troublesome scar. I did the operation, carefully removing the gland and the old cicatrix. The wound healed perfectly, leaving, at first, only a small line. This was several months ago, and to-day not the slightest scar can be seen.

Dr. A. M. Cartledge: First of all, I think it is impossible to treat all of these cases alike. We are all familiar with the different clinical characteristics of gonorrhœal bubo. Where I find surgical treatmeant necessary I have been in the habit of pinching these usually small abscesses up between my fingers and slitting them open. I do not see the necessity for making a large incision in gonorrhœal buboes, and I think they will get well better without it. I seldom make a larger incision than half inch. They are not especially infective, and with this small incision they get well without any perceptible scar. I believe the tendency to scarring is greater with a large incision, removing the gland. In regard to chancroidal and true virulent bubo, I believe I would agree with both sides and yet disagree with both sides in the discussion. I believe if the bubo has attained a considerable size, and you can demonstrate the existence of pus, it should be opened and the pus evacuated. But in doing this in a virulent bubo the wound is liable to become infected and thus prevent its healing. In such cases it may become necessary to remove the diseased glands.

Dr. O. W. Roberts: There are certain conditions of the glands of the groin that we know will go on to suppuration. Chancroidal bubo is one of them. Another is the tuberculous gland when it becomes very much enlarged. I believe with Dr. Rodman that the thing to do is to take them out and to do the operation before suppuration has taken place. If this is done we are almost certain to get primary union. Even if suppuration has taken place and you can remove the gland without infecting the wound with the pus microbe, you are almost sure to get union by first intention and there will be little or no scar. There are other conditions which give rise to these enlarged glands in the groin in which the inflammation can be relieved by properly applied bandage and pressure and which will not suppurate. My experience with gonorrhœal bubo is, if I see a case early and can have the patient wear a compress bandage that they do not suppurate. Where they are allowed to go on without treatment for a week or so, and the patient is "on the go" all the time, they generally suppurate. I rather believe that these gonorrhœal buboes are the result of simple irritation and not caused by the absorption of the pus microbe.

In regard to the opening of these en-

larged glands, I do not agree with Dr. Palmer or with Dr. Cartledge that a small incision is all that is necessary. My experience is that much better results can be obtained by making a free incision and removing all the enlarged glands than by simply making a small incision and trusting to peroxide of hydrogen injections.

CORRESPONDENCE.

THE COUNTRY PHYSICIAN.

Mr. Editor:—

The country doctor is a species of humanity *sui generis;* he is usually born in the country, and frequently begins to practice in the town of his birth. On this account, all other things being equal, he has almost innumerable difficulties to surmount. First, his youth is a serious objection; then his want of experience; and consequently the utter lack of popular confidence.

Time, however, soon makes him older, although he usually assumes all of the characteristics of age at once—raises a full beard and is sure to give his birthday at its extreme cycle of time. Time also brings him patients, and consequently the necessary amount of experience, and the first two objections being removed, he *develops* popular confidence. Now his troubles begin. At first the beauty of the study of medicine fascinated him, then the philanthropic desire to cure all disease was his daily and nightly ambition. But later, when the first glamor has disappeared and he finds that sickness brings out the very worst side of human nature, he clearly realizes the fact that his profession is after all only a means of gaining "bread and butter," and he settles down to hard, steady and weary work for life, or at the very least, for the best of his days.

From his constant intercourse with sickness and death, he soon becomes half philosopher and half fatalist; believing only that which he can clearly see; loth to accept the theory of any one upon any subject until he has an opportunity to verify it either medically, mathematically or by the conviction of his own conscience. Now here is one very palpable reason why so many country physicians never see the necessity of connecting themselves with a church organization; it is surely not because they are not as moral as their fellowmen, neither because they are not "good material," but from the very practice of their profession they are liable, too frequently, to lose faith in humanity, and are thus strongly tempted to doubt the goodness of God.

The country doctor is by no means a follower of Diogenes—the tenets of his profession teach him differently. His knowledge of anatomy alone, should be a firm and sure foundation for a belief in the existence of Deity, and he usually endeavors to follow the golden rule.

In regard to sympathy, let me say there is no class of men who have more real, genuine sympathy for the sick and suffering than the country doctors; he has perhaps known his patients from childhood and many of them are his best friends; much sympathy is frequently hidden by a seemingly indifferent exterior, as it would not be proper to allow it to run away with the judgment.

The doctor, as a rule, never fully shows his true feelings in the sick room; his face is seldom an index of much sympathy; but there is always a warm corner in the heart of every honest M. D. for every sufferer.

The country doctor plods his weary way through the storm and mud of winter; jogs over the dusty roads in the heat of summer; faces the most severe storms for hours at a time; digs his way through snow drifts; reels off the miles over dark and lonely roads, while the farmer sleeps in his warm bed; eats his meals irregularly; has no day of rest, and but precious little time to call his own. I have often thought if the same time and energy was devoted to any other branch of business, a man would accumulate a fortune in five years.

It is almost a wonder that at the age of forty a man engaged in active practice in the country has even the shadow of a constitution, or the slightest resemblance of an anatomy left.

Here is a sample of one day's work: called up at four o'clock a. m. to "pull a tooth;" sees patients in his office until nine o'clock; then a horse is ordered and he starts on his rounds. First he visits a case of typhoid fever; then sees a number of children with scarlet fever or diphtheria; other calls are left for him at the neighbors, and no one knows when he will be able to return—perhaps at dark, to eat a cold dinner. Then another horse is brought to the door, and he hurriedly goes to attend an accident where all of his surgical knowledge and skill are brought into play; he retires at midnight, and before another day appears, he is up and out to attend upon an errand of mercy, as the result of which, the next census shows a new name on the township roll. He begins the day as a dentist, acts as physician and surgeon and closes it as an obstetrician—four branches of medicine in one day.

You may amuse the doctor, but you can never surprise him, and he will be the first to detect any exaggeration. The doctor is a king in his own locality, and is the trusted adviser of hundreds of families; more than mere friendship binds him to the hearts of his patients; "he hears confessions, and keeps them safe, as a sacred trust, like a righteous priest." If he does not receive his reward here below, he is surely entitled to a large share of consideration in another sphere.

The country doctor almost always has a good stock of hard common sense, and some of the brightest lights in the medical world have been born and reared in some little country town.

No one has a better knowledge of human nature in all of its varied characteristics than the village doctor; he has the opportunity of seeing his fellow men in a natural condition; when sickness comes, concealment and deception are cast aside, and poor humanity is seen without the gloss of fashion, policy or self interest.

There are people who have their Sunday face, Sunday actions, Sunday walk, Sunday clothes and some even have their Sunday religion. But when pain and death comes, how natural it is to throw off all dissembling and appear just as we really are; it is then that we lose by comparison.

But humanity is not all satire. I have seen patients die in faith both the Protestant and the Catholic; have seen them meet death with a composure which surely indicated an abiding faith in God, and a belief that Heaven was better than earth.

To the rural practitioner is given an opportunity to enjoy and commune with nature; as he rides through wood and field in summer, he sees the various medicinal plants in bloom and recognizes them as old acquaintances; in the winter he enjoys the setting sun as it casts its shadows of red and blue over the artistically formed banks of snow which line the road, and extend far out in the wide spreading fields. During many a moonlight ride when the temperature was twenty degrees below zero, have I felt, as I dashed over the country in a sleigh, as though I owned the whole earth; the crisp air of a mid-winter night ride is truly exhilarating to both body and soul.

The city physician has a decided advantage over his country cousin. If there is a difficult case or an unusual operation, the city doctor has an abundance of assistants; but the country practitioner frequently performs many dangerous operations alone, or with some bystander as his assistant, and seeing one candle by the light of another. I have amputated the thigh at midnight, with only one miserably frightened girl to hold a lamp; have cut down upon a strangulated hernia without any one to even hold a light; have performed tracheotomy with only the mother of the child present to hold it upon her lap; have delivered women, tied the cord with a string from the window shade, cut it with my pen knife, and washed and dressed the infant—thus acting the part of both doctor and nurse.

The country physician is often obliged to fight disease single handed, when the city doctor has the satisfaction of verifying the aphorism, "in the multitude is safety."

All honor to my brother country doctors! They are indeed indispensable. And fortunate are they if, after having endeavored to be true to their profession themselves, it may be happily said of them

> "A life well spent whose early care it was,
> His riper years should not upbraid his green;
> By unperceived degrees he wears away,
> Yet, like the sun, seems larger at his setting."

JOHN C. HOLMES, M. D.
Cranbury, N. J.

THAT UNFORTUNATE "CONSERVATIVE."

EDITOR MED. AND SURG. REPORTER:

I am far from any desire to raise a controversy in your journal. Such a course would not be of benefit to the profession, to your journal, or to myself. However, I think I am entitled to note the criticism of Dr. Burr, in THE REPORTER for February 18th, entitled "The Advance Guard." It is a quiet, gentlemanly, sarcastic slap at my article in the REPORTER of Dec. 24, 1892, "The Conservative."

I think if the Doctor will look that article over again, he will fail to find a single line that intimates that the competent surgeon, of this or any other country, either specialist or general, is not entitled to all praise and commendation. I think he will fail to find a single objection to *any operation* when necessary. If carefully read it shows, I think, that it is the thinking conservative who makes the most brilliant advances.

Instead of quoting part of Webster's definition—(which he does) given in my article, let him keep all of it in mind. Particularly this—"one who preserves from ruin, injury; a preserver, a conserver." There is not a *good* surgeon but who does claim that his operation is called for by that definition. There is not a *good* physician but bases his treatment on that same definition.

That is what they are *here for*, and hence, according to Webster, all good doctors are conservatives.

But there is another class who are eternally whacking at the conservative as, —as I said,—"a chump, a back number, etc." Waiting one day on a long, slow confinement with no particular features about it, I put in the time reading in a journal one of these shots. Then and there, I wrote the article in what I fondly dreamed was a 'serio-comic' vein. Well! I am either lost on the 'serio-comic,' or my critic Dr. Burr, can't locate the vein.

He quotes from my article this, "the conservative is the fellow who wants to know before he acts." Then adds this—"To reach which point of vantage, one must indeed be a very Solon or phenomenon of learning, or else manifest a large part of his time, a position of imposing masterly inactivity." Now after that, will the Doctor kindly pick up his MEDICAL AND SURGICAL REPORTER of December 31st, and on page 1035, read this from Dr. Jos. Price's article, viz.: "To the inquiry 'who should do abdominal work?' there can be but one answer—the one who has served an *apprenticeship* and *who knows where, when and how.*" Now again, will the Doctor please glance down his own article and read what he, approving, quotes from "Our Philadelphia confrere," viz.: "It is not so much a ponderous dignity and sick room air that we need, but to *know what to do, when to do it and how to do it;*" and then ask himself if there is *any difference* between himself, Dr. Price and my poor "'conservative' who wants to know before he acts." Fact is most of us "want to know" sometimes, more than we can ever know, viz., the certain result of executing what we do know.

Again the Doctor quotes disapprovingly "The conservative is the man who has seen many (old) theories die out, etc., new theories wither, etc. "Well! that's perfectly true, not only as regards medical science, but every other science. Fact is, that statement is very commonplace and has nothing startling about it.

The Doctor says "Medical science originally was a system of baseless theories, bolstered up with spacious reasoning and unintelligible vocabulary." If my critic was an "original" Homeopath, one could possibly understand that position. I think, however, that ever since "Medical Science" could be called a science, the theories of the day were not baseless to the practitioner of the time. Baseless to us possibly, but he was as good as his day and generation and as true to his art, according to his light, as we are.

He erred from lack of a then impossible knowledge, and we learn from his mistakes as we do from our own; and yet,—Glory to his memory! Many of his theories and reasonings still abide with us, to bless and comfort us.

I quote from the annual address of Dr. Clark, president of the Boston Gynecological Society: "In certain cases of sudden occurrence of injury Hippocrates admitted that the spine might be rectified; he rather praises the principle, though he says succussion was chiefly practiced by those physicians who seek to astonish the

mob. To such persons, he says, these practices appear wonderful; people always extol such practices and never give themselves any concern as to the final results." From this it would appear that the old medical saint had been after the 'Radicals' in his day.

My friend writes—"The day is at hand, and even now is, when in place of that, we shall have an *exact science* (italics mine) and an intelligible reason for all things."

At this point I shall have to turn our friend over to you, Mr. Editor, for, on page 823, REPORTER of Nov. 19, you say—"Medicine has not reached the point of an *exact* science, and never will," and I am afraid you are a true prophet.

Dear Dr. Burr—"Shake!" It was all meant for the best, and largely in fun. "The Advance Guard" kept right along after reading it, or possibly took the "Conservative" along for company, and not one of them ever dreamed of accusing me of stabbing *him* under the fifth rib. "Shake" again. Very truly,

S. S. TOWLER, M. D.

Marienville, Pa.

NEW YORK LETTER.*

At his weekly clinical lecture in Bellevue Hospital a few days ago, Prof. Samuel Alexander exhibited a young man who had a primary syphilitic lesion on his penis. The eruption had not yet appeared, hence the only treatment that was prescribed was an antiseptic solution with which to keep the parts clean, and calomel to be dusted on the sore twice a day. Although it was a typical chancre appearing three weeks after intercourse, with its indurated borders and enlarged inguinal glands, no antisyphilitic treatment was given, the professor claiming that it is impossible to positively diagnose syphilis previous to the appearance of the eruption.

In regard to the modern fad for checking syphilis by excising the chancre as soon as it appears, which is extensively practiced in Europe, Dr. Alexander made some rather forcible remarks. He said that, as it is impossible to conclusively diagnose syphilis previous to the breaking out of the eruption, doubtless the brilliant results reported by those genito-urinary surgeons who practiced extirpation, were due to an error in the diagnosis. Although 'tis claimed by many that syphilis is early a local disease, and that by removal of the primary focus the subsequent constitutional disease will be avoided, 'tis not true, for syphilis is a constitutional disease from the first. A reference was made to the case of Barclay Hill, in London; a man came to the doctor two hours after an intercourse in which he lacerated the frænum; he ascertained before leaving the woman that she had syphilis. Barclay Hill washed the wound with an antiseptic solution and thoroughly cauterized it with nitrate of silver; the patient went on his way rejoicing, suffering only from the effects of the caustic. But in three weeks a luxuriant syphilitic eruption appeared.

Dr. Alexander has excised a great many chancres and at a time when all was favorable, the operation having been done early, previous to any inguinal enlargement and with a healthy zone of tissue around the sore, and in no case has he succeeded in preventing the constitutional syphilis.

The operation is justifiable in the case of a married man if the sore is outside on the prepuce and has a healthy zone of tissue around it. He is thus protected from infecting his wife, but the constitutional symptoms will appear as if no excision had been done.

***

At an autopsy in the morgue, recently held on the patient who was supposed to have tuberculous pleurisy, there was found to be a multiple endothelioma in the pleura. During his illness the patient had been tapped eighteen times and at each operation from one to three quarts of bloody fluid was withdrawn from the pleural cavity. The hemorrhagic nature of the fluid suggested either tuberculosis or cancer.

There is but little known of the en-

*Special Correspondent to THE MEDICAL AND SURGICAL REPORTER.

dotheliomata and but few cases of it have been reported. There is no mention of it made in text-books on pathology. These neoplasms seem to occupy the borderland between sarcoma and carcinoma. Their habitat is in the serous membranes. When found in the arachnoid their structure is that of the sarcomata, and when in the pleura nests of cells are surrounded by fibrous stroma, thus resembling carcinomata.

In the pleura of the patient mentioned above, a large number of firm, white, nodular masses were found, the pleura between the tumorous growths being nearly an inch thick. They had been of rapid growth, and seemed to partake of the nature of an inflammatory growth more than that of a neoplasm. The pleura of the affected part, as well as the growths themselves, cut like gristle, and from the cut surface a colloid fluid resembling blood exuded. The cells were large and flattened, resembling endothelial cells.

This form of tumor is very malignant and, attacking, as it does, the tunica vaginalis, peritoneum and other serous membranes, is difficult to diagnose or to treat. No doubt this difficulty of diagnosis accounts for the very few cases that have been reported. As more is learned about this form of tumor it will take a prominent place among the malignant growths with which we so frequently come in contact.

***

At a recent meeting of the Section on Surgery at the Academy of Medicine, Professor W. B. Coley read a paper and presented photographs and patients illustrative of the success obtained in the treatment of malignant growths by inoculating the patients with the virus of erysipelas. He had been actuated to test this method of treatment by observing a patient, who had been operated upon several times for the removal of a cancer which returned after each operation, gaining perfect recovery after having accidentally contracted erysipelas. This was seven years ago and there has been no return of the tumor. The next patient in whom he had tried the treatment was a man with a large sarcoma of the neck which had been operated upon without success. Dr. Coley injected erysipelas buoillon-cultures into the tumor a couple of times; it soon wasted away and there has been no return. He has studied this method of treatment in thirty-four cases, seventeen of which had carcinoma and the remainder sarcoma. Three of the cases of carcinoma and seven of the sarcoma permanently recovered. Of the remainder all showed marked improvement except one who died accidentally, and another who died as a result of the erysipelas.

Dr. Coley explained the good results obtained as due to an antagonistic bacteriological action, and that its effects were constitutional, as growths in parts distant from the place where the virus was injected disappeared.

In the discussion which followed Dr. Bull said that he could confirm the report of the case presented by Dr. Coley. He thought, however, that this plan of treatment had its dangers and was far from perfect, but that it might prove a valuable adjunct to surgical procedure.

Dr. Daniel Lewis thought that erysipelas acted by its local irritative and destructive effects, the same as preparations of arsenic and other caustics; and that the efficacy of this plan of treatment should be more extensively tested before it could be generally adopted.

Dr. John A. Wyeth thought that the specific germ of erysipelas might have a peculiar influence on malignant growths, but that other kinds of inflammatory action often effect a cure. He spoke of one of his patients who had a sarcoma of the abdominal wall which was too large to remove, in whom a complete cure was obtained by injecting arsenious acid into and around the growth. Microscopical examinations by prominent pathologists conclusively proved the tumor to be a true sarcoma. This was done seven years ago and there has been no return.

Dr. Coley concluded the discussion by saying that erysipelas could not effect its results by local irritative influence, as in one of his cases a malignant tumor in the vagina, far from the seat of injection, had been cured. As he had tested it in seventeen cases of inoperable sarcoma, and obtained seven cures, he thought the sooner the public knew of it the better.

Hydrochlorate of apomorphine is now said to be the agent responsible for all the ill-effects of the Keeley "bi-chloride of gold" cure.

EDITORIAL.

GYNECOLOGY AMONG THE INSANE FROM ANOTHER POINT OF VIEW.

Whatever motive may have inspired the action of the State Board of Public Charities to condemn and interdict in a most sensational and public manner, the use of surgical methods of relief among the inmates of the female department of the State Asylum at Norristown, the folly of its haste is daily becoming more apparent. Whether it was done to influence proposed legislative abridgment of its powers, or whether some unworthier animus impelled, does not particularly concern the present question, save that it goes far to show the desirability of abolishing the Board or, at least, limiting its duties to matters within its understanding—which is equivalent to abolition.

While to the general public the report furnished a passing sensation and an opportunity to add another to the long list of imaginary horrors and abuses practised by the medical profession upon defenseless subjects, to the Profession it offered several questions of profound importance. The incident has been commented upon by many professional journals, generally from the point of view of the State Board, and consequently with the same amount of information and judgment.

THE REPORTER has from the start sustained the action of the physician-in-charge in treating the patients as her best judgment, backed by the best opinions she could obtain, dictated.

THE REPORTER presents without further comment than its full endorsement, the reply of the Board of Trustees of the Norristown Asylum to the State Board of Public Charities. The reply, carrying with it a stinging rebuke to the meddlesome exercise of questionable authority, includes the report to the Trustees by Dr. Bennett, giving a full record of each case. Dr. Bennett's summary is the best presentation of the subject yet offered, and deserves the closest attention of the entire profession.

STATE HOSPITAL FOR THE INSANE,
S. E. District of Pa.

NORRISTOWN, February 3d, 1893.

To the Board of Public Charities,
State of Pennsylvania.

GENTLEMEN: At the first meeting of the Board of Trustees of this Hospital

after the receipt of your communication of December 10th, 1892, the Chief Physician of the Department for Women was directed to furnish a detailed report of the surgical operations alleged by you to have been performed in this Hospital for the cure of insanity.

We submit, herewith, her report upon six cases, the only operations of the kind ever performed in this Hospital.

You will see that, in this case, the operation was performed as the best judgment of the Medical Staff, to relieve suffering and to remove organs so much diseased as to no longer perform their functions; the question of sanity or insanity not being considered, insanity being regarded as a symptom and not a disease.

This Board has exercised great care and deliberation in the selection of its Medical Staff and, on purely medical matters, it does not profess to interfere with the judgment of the physicians in charge, believing that they have all the opportunities for judging correctly of the necessities of each case and the proper mode of relief.

If your committee will express to this Board its want of faith in either the skill or judgment of any of the Medical Staff, we shall give the matter immediate attention.

In connection with this matter, we would state that Dr. Morton, chairman of your Committee on Lunacy, was fully cognizant of the facts, as will be seen by the following letter from him to Dr. Bennett, congratulating her upon the success of one of the operations performed in July, 1892, which was long prior to your communication to this Board.

(*Copy of Dr. Morton's Letter.*)

DR. MORTON,

1421 CHESTNUT ST., PHILADELPHIA.

Dear Doctor:

I thank you for the opportunity for examining ———. She looks and seems perfectly well and I congratulate you upon the result. Sincerely,

THOMAS G. MORTON.

DR. BENNETT.

We certainly think that, after such an indorsement, it is unfair for your Board, arbitrarily, without notice and without an investigation for each case, to charge that our work was experimental, and we know that the term used by your Board in calling these operations "Removal of Ovaries as a Cure for Insanity" was not warranted by the facts.

So far as the opinion of your legal member, Mr. Barlow, is concerned, being based upon wrong premises, it has no bearing upon the matter.

A careful examination of all the facts warrants the Board of Trustees in concluding that the operations were in the interests of humanity. The report of your Committee is evidently based upon a misapprehension of the facts, and we cannot withhold the expression of our regret that your Honorable Board has, without due investigation, not only judged and condemned our work, but that it has also thought proper to give wide publicity to a judgment based upon unwarranted assumptions.

We, therefore, respectfully ask that you will reconsider the resolution directed to this Board.

Very respectfully yours,

C. H. STINSON, GEORGE ROSS,
ELLWOOD M. CORSON W. D. H. SERRILL,
EDWIN G. MARTIN, JOSEPH THOMAS,
ISAAC ACKER, J. M. HACKETT,
WM. J. ELLIOTT, SAM. S. THOMPSON,
BARTON D. EVANS, JOHN T. DYER.

(*Report presented to Board of Trustees, Feb. 3, 1893.*)

STATE HOSPITAL, DEPT. FOR WOMEN,
February 2d, 1893.

To the Board of Trustees.

GENTLEMEN: In obedience to your request, I beg leave to present the following condensed histories of the six cases in this department which have been the subjects of ovarian operations.

CASE 1.—Age, 49 years; American; married; mother of four children, of which the youngest is 18 years of age. The first attack of mania followed the birth of her first child, 29 years ago. The present attack is the fifth and came on about two months before her admission to the Hospital, May 24th, 1892.

Mental Condition: Mania of a mild type with delusions.

Physical Condition: General debility with anæmia, small amount of albumen and mucous casts in the urine.

Internal Examination showed uterus retroflexed and drawn to left side. The attacks of insanity had always been preceded by periods of severe pain in the region of the left ovary.

Operations done July 3rd, 1892, by Dr. Marie B. Werner assisted by Dr. Joseph Price; there were present Dr. L. McMurtry, of Louisville, Kentucky; Drs. Kollock and McAllister, of Philadelphia; Drs. Bennett, Taber, Willits and Lothrop, of the Hospital Staff.

Both ovaries and tubes were removed by abdominal section.

Condition of Organs Removed: Left ovary and tube contained many small cystic tumors. Right ovary cirrhotic, with calcareous deposits; tuberculous degeneration of left tube.

Result: Patient recovered rapidly from the operation, and she went home completely restored in body and mind on the 6th of August, a little more than four weeks after the operation.

Case 2.—Age, 28 years; American; white; single; apparent family predisposition to insanity. Patient had lived an irregular life, and was said to have suffered from internal trouble, dating from an abortion produced five years before. Admitted to Hospital, August 28th, 1888.

Mental Condition: Melancholia, with stupor, for the first year; for the following three years, lucid intervals, alternating with periods of violent maniacal excitement, during which she became profane, obscene, destructive and suicidal.

Physical Condition: General condition poor on admission; urine contained albumen and hyaline casts.

Internal Examination showed uterus prolapsed, enlarged and fixed; profuse secretion; masses felt in region of both ovaries, sensitive to pressure. Much localized pain suffered at times. No permanent improvement followed local treatment.

Operation done at same time with Case 1.

Ovaries and tubes on both sides removed by abdominal section.

Condition of Organs Removed: Hydrosalpinx of both sides. Adhesions of extraordinary firmness, roofing in the pelvis and binding tubes, ovaries and adjacent tissues in one mass, of which the parts were almost indistinguishable.

Result: Recovered rapidly and went home well physically and mentally, on the 17th of September, 1892.

Note: This patient was subsequently examined by Dr. Morton, who wrote to congratulate me upon the result.

The patient, herself, wrote October 12th: "I have not any of my old pain, and I think the operation I passed through has improved my health ten-fold. I feel as though I could not thank you enough for your kindness."

Case 3.—Age, 24 years; married; admitted July 5th, 1892.

Eight months before admission, being then in the fourth month of pregnancy, she fell to the floor in convulsions, which lasted four hours; these were followed by some impairment of mind and occasional fits, premature delivery was induced two months later, without much benefit. From February to June she was in the "Friends' Asylum."

Mental Condition: Periods of maniacal excitement with delusions, alternating with longer intervals during which she was almost, if not entirely, well. Had five epileptic fits during the months of July, August and September,

Physical Condition: General condition fairly good.

Internal Examination showed right ovary prolapsed and enlarged; acute pain on pressure; mass felt on left side and in posterior cul-de-sac.

Operation done on October 13th, 1892, by Dr. Joseph Price, assisted by Dr. Willits and Dr. Bricker. There were present Drs. E. M. Corson, and S. N. Wiley, of Norristown; Drs. Bennett, Taber, Lothrop and Wilmarth, of the Hospital Staff.

Ovaries and tubes of both sides were removed by abdominal section.

Condition of Organs Removed: Both right and left ovaries contained numerous small cysts. Right ovary also contained a larger cyst, the size of a walnut.

Result: Rapid recovery from operation. No fits since October. Mental condition about as before.

Case 4.—Age, 17; American; white; single; admitted April 12, 1892.

History not very definitely obtained, but mind probably affected for some months preceding. Father thinks that she was never the same after baptism by immersion, the preceding summer. She had left her home and otherwise acted peculiarly.

Mental Condition: Mania, with delusions; at times much excited and destructive, principal delusion that she was pregnant. Improved and went home, on trial, August 18th; returned September 16th, in a condition of stuporous melancholia; had to be carried into the ward in her father's arms; required to be fed and cared for like an infant; slight improvement during the following month.

Physical Condition: General condition poor; but improved under tonics. Urine contained traces of albumen.

Internal Examination: Uterus retroflexed and fixed. Excessive tenderness on both sides; regular local treatment produced little, if any effect. Menstruation painful and scanty.

Operation done at same time with Case 3.

Both ovaries and tubes removed by abdominal section.

Condition of Organs Removed: Ovaries cystic. Both ovaries and uterus in a singularly undeveloped condition, the former apparently devoid of ordinary ovarian tissue. It was the opinion of Dr. Price that these rudimentary organs could never have performed the functions pertaining to them, and it is reasonable to suppose that the periodic struggles of nature to perform functions, to which these undeveloped organs were inadequate, produced profound disturbance of the nervous system.

Result: Recovered promptly from the operation and went home well, physically and mentally, November 16th.

The change in this patient was very remarkable, and observed by all about her. Not only was there a marked improvement and development of her physical system, but, mentally and morally, there was a striking change for the better. Her father writes January 25th: "If you would see her, and see how she helps about, you would think that she had never been sick." The patient, herself, writes February 1st: "Indeed I will never forget your kindness in getting me so well as I am, and thank you so much for what you have done for me."

Case 5.—Age 36; American; white; married; had attack of mild melancholia, following the birth of her

first child, four years before, from which she recovered in this Hospital. Present attack came on one week after the birth of the second child. Admitted to the Hospital December 4th, 1888.

Mental Condition: Attacks of violent mania, alternating with about equal periods of a more quiet condition. The violence of maniacal attacks increased during the four years, until she came to be considered the most dangerous patient in our violent wards. The excited periods became a sort of frenzy; she was not only a wild, destructive and aggressive, but also very suicidal.

Physical Condition: General condition fairly good; urine at times contained albumen and casts.

Internal Examination: Laceration of cervix uteri, bilateral; left ovary acutely painful on pressure, and ligament on that side shortened. Subject to periodical, exhausting hemorrhages.

Operation done Oct. 23d, 1892, by Dr. Joseph Price assisted by Dr. Willits and Dr. Bricker. There were present Drs. E. M. Corson and S. N. Wiley, of Norristown; Dr. Katherine Kollock, of Philadelphia; Drs. Little and Mayo, of Minnesota; Dr. Parker, of Indiana; Dr. Jennings, of Virginia; and the entire Hospital Staff.

Ovaries and tubes of both sides were removed by abdominal section.

Condition of Organs Removed: Cystoma, the size of a hen's egg, in both right and left ovaries; ovaries otherwise cystic.

Result: Patient made a slow recovery from the operation, on account of suppuration around the stitches; transferred from the farm-cottage to ward, November 25th. Mental condition very greatly improved and [Feb. 2d,] still improving, has no violent attacks, takes an interest in all around her and helps constantly in the work of the ward; disposition amiable and seems happy. I think it possible that this patient may entirely recover, notwithstanding the long duration which is always an unfavorable element.

Case 6.—Admitted to Hospital, September 9th, 1886. Age, on admission, 40; Irish; mother of seven children, of which the youngest was three months old; seven weeks after the birth of this child, became violently insane.

Mental Condition: On admission, melancholia, with periods of frenzy. With improved general health her mental condition also improved so that, for the last three years or more she was perfectly well, except during her periods of maniacal excitement which were coincident with the catamenia.

Physical Condition: On admission, generally poor, but improved under tonic treatment. Urine, at times, contained albumen and casts.

Internal Examination: Laceration of cervix uteri, bilateral; uterus not freely movable; thickening of left broad ligament and acute pain on pressure of left ovary.

Operation done at same time with Case 5.

Ovaries and tubes of both sides removed by abdominal section.

Condition of Organs Removed: Both ovaries cystic. Left ovary contained tumor the size of a walnut, which, in spite of the utmost care, ruptured during removal; Dr. Price was of the opinion that this tumor was liable to rupture, and discharge its contents into the abdominal cavity, at any time during life, and that its presence was thus a constant menace to life itself.

Result: Patient died on the sixth day of peritonitis.

To SUMMARIZE: Of six cases operated upon, three, or half the number, have perfectly recovered in body and mind. One is much improved. One is improved in some respects and not in others. One died.

It is of interest to note that five of the six, were of puerperal origin.

I want to emphasize the following facts:

(1) That cases were selected for operation only after thorough and searching examination, with consultation, often repeated.

(2) That each case selected for operation was the subject of serious bodily disease, such as may properly be, and habitually is, treated by surgical interference, quite apart from the insanity which is only an incident, or symptom, of such disease.

(3) That in every case of operation performed, the consent of the nearest relative, or guardian, of the patient was obtained.

(4) That no cases, other than those detailed above, have been at any time selected, or set apart, for operation.

Finally, I want to say that I believe that many cases now under our care, and others yet to come, might be saved from years of physical suffering, from hopeless dementia, even life itself might sometimes be saved, by appropriate surgical treatment. The study of Case 5, is to me inexpressibly sad. This unhappy woman should have been spared these four years of unspeakable suffering, and her complete restoration assured, by an earlier operation for the removal of organs diseased beyond the hope of recovery. I am conscious that my full duty toward her was not done.

In other and similar cases in the future I cannot reconcile it to my conscience to be merely a passive observer and recorder of their decline. If, in Pennsylvania, insanity is to be a barrier to the treatment of bodily diseases, it will be my duty to urge upon the guardians of these helpless ones, incapacitated for speaking on their own behalf, the necessity for taking their suffering charges, outside the state limits if need be, wherever they shall be free to receive the treatment adapted to their needs.

Very respectfully yours,

ALICE BENNETT.

TRANSLATIONS.

THE ABUSE OF MILK IN ALBUMINURICS.†

Lecorché and Talamon, (*La Médecine Moderne*, Jan. 14, 1893) dwell upon the abuse of milk in the management of albuminuria. According to them the treatment of albuminuria by the majority of physicians assumes a single and unchangeable form, namely, the milk diet. This forms in their minds a sort of algebraic formula, *albuminuria=milk*, the first term of which necessarily calls for the second. Every individual afflicted with albuminuria is, *à priori*, condemned by them to milk for the future. Without that no recovery and no treatment. They believe that they have done everything when, having found albumin in the urine, they prescribe without other procedures milk, only milk and always milk. True, milk is the medicine *par excellence* for nephritis, and its usefulness in albuminuria cannot be disputed. But it is a medicine which has its indications and its contra-indications as every other medicine, and it is as unreasonable to give milk to every individual who has albumin in his urine, as to prescribe digitalis to every person who presents a heart murmur.

The abuse of milk has for its basis the special idea emanating from the physiological axiom that milk is a perfect food. That milk is a food, and a perfect food, is granted, but the milk diet is not an alimentation. In other words, after the first infancy man is not constituted to live exclusively on milk. One liter of milk contains on an average 37 to 40 grammes of albuminoid material, 40 grammes of fat and 50 grammes of hydrocarbons. The daily ration of an adult being fixed at 125 or 130 grammes of nitrogenized principles, 100 grammes of fat and 300 grammes of hydrocarbons; it can be seen that if three liters of milk suffice to complete the sum of the nitrogenized and fatty principles, six will be necessary to furnish the sufficient quantity of hydrocarbons. In admitting that the considerably greater proportion of fat and albuminoids compensates for the deficit in the hydrocarbons, theoretically, therefore, four liters of milk daily should provide for the needs of the organism. What stomach is able to absorb indefinitely this quantity of milk without disgust and fatigue? Therefore, either the patient cannot take the necessary dose, or if he succeeds in obeying strictly the imposed prescriptions, the digestive tube revolts, and gastro-intestinal complications are produced. In two ways it tends to insufficient nutrition, general weakening and anemia. But to go further. Even suffering the daily dose to be tolerated and digested, is this dose actually equivalent to the ordinary ration of meat and vegetable foods? Milk debilitates. Look at a patient submitted for some time to an exclusive milk diet; his complexion is pale, his flesh is flabby, he is incapable of active cerebral work, and of all prolonged muscular effort. He has lost entirely his physical and moral energy. The chemical equilibrium is satisfied, but the vital equilibrium is not. Is it because the albumin of milk is different from the albumin provided by other nitrogenized materials? It is not known, but neither is it known why milk improves a vicious nutrition. This intimate action that is not known is without doubt the same in the two cases, favorable when the organism is surcharged with the products of an excessive fleshy alimentation, unfavorable when it is deprived for a long time of these same products. In fact, if the milk diet is a sufficient alimentation for a bedridden person, it is an insufficient alimentation for a healthy and active person. Now, three-fourths of the albuminurics are for months and years active patients whom we can have no reason for condemning to inaction. Therefore, when milk is prescribed for an albuminuric it is not as a food, but as a medicine and, therefore, as all drugs, its employment demands to be watched; given at the wrong time it may be useless or become dangerous.

In a general manner to order the milk diet in the period of remission of Bright's disease in albuminurics, who do not present other morbid conditions than the presence of albumin in the urine, when

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

the quantity of water is above the normal or even simply normal, when the solid constituents, urea, uric acid are in normal proportion, is unreasonable. If the hope is to cause the trace of albumin still shown by the urine to disappear it is vain. When the milk has quieted the acute irritation of the kidney, or re-established the circulatory activity of the organ when, by determining polyuria, it has prevented the dangers of accumulation in the blood of the principles which ought to be eliminated by the urinary secretions it has done all that it is able to do. If its usage is greatly prolonged the albuminuria cannot be made to disappear completely.

Surgery of the Biliary Passages.*

Dr. A. Frænkel made the following studies and observations during his service at the Rudolfinerhause, of Vienna. He first calls attention to the fact that it was Lauenstein, at the last Surgical Congress at Berlin, who first called attention to an apparently forgotten complication, i. e. adhesions at or around the region of the gall-bladder which frequently simulates biliary colic, and that the releasing of these adhesions will promote the cure. He cites two cases in which he assisted Prof. R. Gersuny, in which the previous histories had been exactly those of grave biliary colic, in which, however, no calculi were found, only various long bands of adhesions extending from the neighboring omentum to the region of the gall bladder. He emphasizes region of the gall-bladder since they found in each case a defect of the gall-bladder. One case was that of a colleague who had suffered for six years, from periodical attacks of colic, which presented the usual picture of that from gall-stones. There was but one symptom missing, namely, the retention of the gall in the gall-bladder which usually forms a palpable tumor at the border of the liver. A varying but not grave form of jaundice and a swelling of the liver of about three finger breadths was all that could be demonstrated by examination in both patients. Each case began with nausea and pain in the region of the stomach, extending later to the region of the liver. The attacks lasted usually from two to three hours, extending themselves latterly from twelve to fourteen hours in the case of the colleague. The second patient gave a history of having had the attacks last from twelve to fourteen days, and stated that he frequently had seen in his stools masses looking like black sand which had been declared by the physician in attendance to be small gall-stones. In neither case was it possible to find in any of the canals, a stone, while in one there was but a band which seemed to originate in the normal position of the gall-bladder. The second patient possessed a thin walled, translucent and not enlarged gall-bladder whose lower extremity was tightly adherent to the omentum which ended in a band-like prolongation behind the liver. The operation consisted in separating these adhesions and drawing the peritoneum over the stump with silk sutures. The result was in both cases satisfactory. The patients are free from pain and enjoying perfect health. The author wishes to refer the reader to the practical and important points these cases present—that Cholelithiasis can be produced through the residue of previous inflammatory processes, and which may probably have its origin in gall-stone troubles, and also through diseased processes called forth from affections in the region of the gall-bladder. He thinks that in grave cases referring to the gall system, even though a strict diagnosis cannot be made, an exploratory operation might be of great use. There is a further lesson which these operations present, that of covering all stumps as much as possible with peritoneum in order to prevent any adhesive complications following. This was very clearly shown in an address to the Surgical Congress by Winiwarker who presented a case in which he had to perform repeated sections after an ovariotomy, in order to cure severe colics which had their origin from such bands of adhesions.—*Central f. chirurg*, 1892.

Surgery of the Gall-Bladder.*

Dr. Carl Lauenstein, of Hamburg, says: At times the surgeon after making the incision finds the gall-bladder so contracted that it lies beneath the liver, making it impossible to see its outer margin. For such cases where it becomes necessary to

*Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

*Translated for the Medical and Surgical Reporter by Marie B. Werner, M. D.

do the operation at one sitting, Riedel has proposed that the peritoneum should be loosened with or without the transverse fascia in the region of the abdominal wall, and its ends attached to the gall-bladder, forming in this way a funnel-shaped canal through which the contents of the gall-bladder can pass directly outward. This proposition of Riedel, which the author has been able to use in several instances is according to his views, of great importance in certain cases. He further states that among nineteen operative cases he found but two in which the contracted gall-bladder was so deeply situated that even following Riedel's method, it was impossible to prevent some of the gall or pus from entering the general cavity. In these cases the author found it useful to raise the large omentum over the transverse colon, drawing it at its free end to the gall-bladder, stitching it fast to its margins and in this way producing the canal for its safe passage. The author found in both cases a desirable result, which makes him feel it practicable to use the large omentum as plastic material for such purposes.—*Central. fur. Chirurg.*, 1893.

Three Cases of Cæsarean Section for Eclampsia.*

Wertheimer presents in his dissertation the importance of rapid delivery in antepartum eclampsia. In the early stages, however, while the os uteri is still closed and the cervix still intact, there has always been a difference of opinion. He feels he would follow the method of Halbertsma in particularly unfavorable cases of eclampsia in which immediate delivery is impossible, to produce relief by the Cæsarean section. He considers it necessary to study the number and intensity of the attacks, the gravity of the coma and the condition of the lungs, heart and kidneys, before deciding upon the latter mode of relief. He gives an account of three cases in which after careful application of all the above methods and a fruitless morphia narcosis, Cæsarean section was resorted to.

The immediate results in all three cases were good for both mother and child. In the first case, the mother succumbed to miliary tuberculosis after eleven days, and in the third case, the eighth-month child died on the third day. In opposition to Löhlein and v. Herff, who present as first consideration the Cæsarean section for a living child, W. would still like to see this method practised in cases where the death of the child has taken place, but in which there is no change for the better in the mother. In the sixteen operative cases up to the present time, ten mothers were saved. In closing W. mentions Dührssen's method, which consists of a bloody dilatation of the cervix, respectively a combination of the bloody with the mechanical dilatation, the last with the aid of a Colpeuryter. The latter method, the author concludes, to be more dangerous than the Cæsarean section, while the first is without doubt void of danger.—*Wertheimer, Wiener klin. Wochen,* 1892.

Some Observations upon Pathologico-Anatomical Changes in a Case of Tetanus Traumaticus.

T. Ventori, (*Central. f. Allgem. Pathology and path. Anatomy,* 1892.) In the case of a deceased man who had suffered from an injury to his right foot, after which followed tetanus, a pathological investigation showed the nerves of the hip intact but various degenerative changes in the lumbar region of the spinal cord, particularly at the roots of the spinal nerves which merge from the middle and lower portion of the lumbar enlargement. The columns of the spinal cord had met with but slight changes. Bonome found in two cases of traumatic tetanus the same conditions—the principal changes at one point or segment of the roots of the spinal nerves showing a strong line of demarkation, and which stood in some connection with the point of infection. In all other portions of the body the nervous system showed marked hyperæmia. Changes of lesser gravity in connection with the point of infection of the virus are also seen in the nerves and the segments of the spinal cord in cases of hydrophobia.

Ventori found in a case of hydrophobia, (following a bite in the right hand), a marked swelling of the throat and progressive degenerative changes in the spinal cord.

ABSTRACTS.

RECURRENT EARACHE.

The necessity of finding the cause of recurrent earache which subsides without apparent injury to the ear. In writing on this subject Dr. Woods of Baltimore says:

No physician of considerable practice can have failed to have patients consult him on account of recurring earache. In some cases the pain comes in paroxysms of two or three hours' duration; disappears, sometimes spontaneously, sometimes only after the use of hot applications and anodynes; and returns after a long or short interval. Again, there are no distinct paroxysms of pain. The individual is conscious now and then that his ear hurts him. It never confines him to the house, and he may make only an incidental allusion to it when he happens to feel a pang, or thinks of the matter when with his physician. While by no means always so, the first class is usually made up of children, the second of adults. One will find, I think, that the subsequent histories of such cases divide them into three groups: (1) those who "outgrow," as it is called, the earache, or at any rate cease to have the attacks, and retain good hearing; (2) those who continue to have occasional paroxysms, or else now and then feel a twinge of pain, without the development of any special symptoms save a slight, and possible transient, defect in hearing; (3) those who after an attack of earache have a serous or purulent otorrhœa. This may subside and leave the ear still useful, but nevertheless impaired; or it may become chronic.

Thus earache may be a trival matter. Again, it may be a symptom of an inflammation, which will soon show itself by a discharge; or else be the only appreciable indication of conditions which can cause slow changes in the ear and lessen its usefulness. If the diagnosis "earache" be looked upon as good and sufficient, and therapeusis be limited to relieving the patient's suffering, *possibly* no harm will be done; but in the majority of cases important things will be overlooked, and harm will result.

Barring furuncular and diffuse inflammation of the external auditory canal, painful affections of the ear are due, usually, to catarrhal inflammation of the tpmpanic cavity, or to reflex neuralgia of the ear from some cause outside of the ear itself. Canal inflammation generally shows itself clear enough and need not be considered. Of catarrhal inflammation of the drum cavity, many cases pursue the typical course of hyperæmia of the tympanic mucosa, exudation into the drum cavity, perforation of the drumhead, and the establishment of an otorrhœa. Pain is the most prominent symptom of the stages of hyperæmia and exudation, and is relieved when the drumhead ruptures. But all cases do not go so far as perforation.

Tympanic hyperæmia may occur once or twice as the result of cold or exposure, and subside without serious results; but when it occurs again and again two things become manifest: (1) the usual results of repeated hyperæmia will probably ensue in the tympanic cavity, and (2) there must be some cause of these attacks more or less closely connected with the ear. That acute catarrh of the tympanum is the most common cause of the repeated earaches frequently observed in children, is the opinion of such authors as Woakes, Roosa and Buck; but the pain soon subsides, the hearing continues good, and nothing more is thought of the matter till the next attack. If more care were taken to make the tests, there is little doubt but that the hearing of ears which have passed through two or three such attacks would be found impaired. Still, as one can lose nearly one-half of the normal hearing power without being specially inconvenienced, the slow deterioration is not noticed for a long time.

Chronic abnormalties of the nasopharynx are a prolific cause to tympanic catarrh. Follicular pharyngitis, postnasal vegetations and hypertrophied tonsils are, in my experience, the most common throat lesions observed in connection with recurring earache. It is, I think, a more or less common belief that, if chronic follicular pharyngitis does not cause so much throat discomfort as to call attention

to itself, or if post-nasal adenoid vegetations do not interfere with nasal respiration, these troubles may be left alone. That they can produce deafness and recurring hyperæmia of the tympanum without special throat or nasal symptoms, I do not think admits of doubt. Situated, as they often are, near the pharyngeal mouths of the Eustachian tubes, these inflamed follicles or vegetations act as irritants, increase the vascularity of the tubes, and cause an Eustachian catarrh. This can reach the tympanum by direct continuity of mucous membrane. Again, as soon as ventilation of the tympanum through the Eustachians is hindered, and the air already in the tympanum has been absorbed—no renewal taking place through the tubes—atmospheric pressure in the external canal drives the drumhead inwards, producing undue pressure upon the ossicles. Impairment of hearing and tinnitus usually follow at once. If unrelieved, hyperæmia and pain follow. Relief comes as soon as the Eustachians again admit air to the drums. Inflation by Politzers's method promptly removes the ear symptoms, and the application of a nitrate of silver solution to the mouths of the tubes lessens the secondary catarrh; but it will surely return, unless the primary trouble is removed. As regards enlarged tonsils, their importance from an otological standpoint has been exaggerated. Probably they rarely occur unaccompanied by other morbid conditions of the throat, which more immediately affect the ear. By lessening the air-space, they may, indeed, produce these conditions. This will certainly be the case if they interfere with nasal respiration. The same is true, however, of any conditions which block the nostrils. Mouth-breathing is a well-known cause of pharyngeal disease, and when nasal respiration is impeded in persons suffering from ear symptoms, it should be re-established. Still, so far as the *direct* influence of hypertrophied tonsils upon the ear is concerned, Roosa states that it is doubtful if they ever enlarge to the extent of pressing upon the mouths of the tubes. He advises their removal upon the grounds I have advanced: that they may "affect the health of the pharynx." I have seen patients cured of middle ear disease by the removal of post-nasal vegetations, although hypertrophied tonsils were also present. Another source of danger to the ears from naso-pharyngeal disease is direct microbic invasion through the tubes. This undoubtedly occurs.

The teeth, and more particularly dentition, constitute a source of ear disease which is not sufficiently appreciated. The occurrence of otorrhœa in babies during dentition is frequently observed. Earache in infants, I am sure, is not always recognized as promptly as it should be. I see babies with otorrhœa whose clinical history is very clearly read backwards from the otorrhœa to dentition, but the pain the little one then had in the ear was not attributed to that organ.

Sexton, of New York, who has given the subject of oral irritation careful study, considers irritation from the mouth a most prolific cause of ear disease. He goes so far as to condemn amalgam fillings, vulcanite plates, and retention of teeth which have lost their nerve pulp, as dangerous to the integrity of the ears. I have tried to make some clinical observations upon this subject. While I have seen nothing to lead me to accept all Sexton says, I have over and over again seen earache, sometimes accompanied by hyperæmia of the drumhead and sometimes not, cured only after a carious tooth has been removed, or cleaned out and filled.

The channel of transmission from the teeth to the ears may be directly through the fibres of the fifth from the dental to the auriculo-temporal branch. This may be the case in those patients whose trouble is only *pain* of a reflex character, unaccompanied by inflammatory changes; but it will not explain the acute aural catarrh and suppurative otitis of dentition. Two explanations of these lesions are given: (1) extension of the inflammation from the gums to the middle ear by direct continuity of tissue. Roosa says he has seen this. Woakes, on the other hand, holds that the intermediate tissues are healthy, and offers, as an explanation of the tympanic catarrh, (2) vaso-motor disturbance.

Justifiable conclusions from the foregoing are, that the diagnosis in cases of recurrent earache must include the condition of the drumhead, pharynx, nose and teeth; that therapeusis must include the treatment of disease found in these structures.—*Maryland Med. Jour.*

Hahnemann's "Organon of Medicine" published the basis of homeopathy, 1810.

SURGICAL TREATMENT OF EPILEPSY.

Kümmell * reports ten cases, in which various operative measures were employed in the treatment of epilepsy, and reviews the various methods which have been suggested. He collects forty-five cases, where Alexander's operation of tying the vertebral arteries had been done. Eight of these gave distinctly good results; in eleven the condition improved; nineteen were not benefited, and in seventeen the result was unknown. To these, he reports two cases of his own in which the vertebrals were tied, first on one side and then on the other, but with only an extremely transitory result. In this operation the possibility has been suggested that all the fibres which pass from the superior ganglion of the sympathetic were cut off by the ligation, and hence Alexander himself has advised the removal of the superior cervical ganglion. This was done in one of Kümmell's cases, but here again the result was merely temporary, and after the operation of tying the vertebral and removing of the ganglion, the condition gradually grew worse. In four cases of epilepsy, where there was no history of previous trauma, and where the attack pointed to no special motor center in the cortex, he trephined over a tender spot in the skull. In these cases he found no perceptible changes at the point of trephining. The first two cases were materially improved; the second case was merely relieved of the tenderness; the fourth case, which presented more the features of petit mal, improved as to the psychical condition, although the attacks continued in a less severe form. Three cases presented distinct cortical epilepsy; in one, a portion of thickened dura was removed, and the patient had been for three and a half years without an attack; the second case presented spasm in the right arm and face, no physical changes were found in the brain except a possible projection in the inner portion of the skull; here no benefit was obtained, but the author regrets that a portion of the cortex was not also removed; a third case was of traumatic origin, and presented spasm in the right side of the face and the right arm; the thickened dura was removed, and the case has thus far continued well.

* Deutsche Med. Wochenschr., June 8, 1892.

Gerster and Sachs † report ten cases of epilepsy where trephining was performed, seven of which were truamatic, one due to hereditary disease, one a case of infantile cerebral hemiplegia, and one a case of non-traumatic localized epilepsy, due to early acute brain disease; one case showed great improvement; three, slight improvement, and one showed a little improvement immediately after the operation, but the attacks returned. In every case, however, the attacks recurred after a lapse of several months. Sachs claims that the excision of cortical tissue of the diseased area is not superior to the older method of simple trephining, though a focus of disease may be the actual case of epilepsy. Epilepsy, as a rule, does not manifest itself until widespread changes have appeared throughout the entire brain. If, therefore, we operate upon cases which have run a course of many years, removal of the initial focus of disease will have little effect upon the general sclerosis that has been established. He, therefore, suggests prompt surgical interference in all cases of injury to the skull where there is any reason to suppose that harm has been done to the brain, and also in those cases where a localized hemorrhage of traumatic origin, is more than likely to give rise to epilepsy; later on, excision of the cortex seems a questionable method. If patients could be promised a freedom from future attacks, excision might compensate for the paralysis caused by such excision, but such a promise can scarcely be given except in the most acute cases. Although the prospects for much benefit are gloomy, yet, considering the seriousness of epilepsy and the slight danger attending the opening of the skull, Sachs believes it the surgeon's duty in every case in which there is a shadow of doubt about the effect of an injury to the skull or brain, to trephine the skull and thus remove the cause of an epilepsy about to be developed.—*Bost. Med. and Surg. Jour.*

A Chicago Surprise.—Lakeside—So Winkle has lost his wife.

Whistler—Dear me! Who has got her?

Lakeside—Death.

† Amer. Med. Jour. of the Med. Sciences, November, 1892.

Exophthalmic Goitre.

P. J. Möbius, (*St. Petersburg Med. Wochenschrift*) has collected the main symptoms occurring in this disease from the widely distributed literature on the subject:

1. Examinations of the eyes shows exophthalmus, unusual space between the lids (Stellwag's sign), retardation in the movement of the upper lid (Graefe's sign) insufficiency of convergence, frequent paralysis of the ocular muscles of an intra-cerebral character, tremor of the eyelids and nystagmus.

2. Examination of the heart shows increase in frequency, systolic murmurs at base of heart, cardiac weakness and angina pectoris.

3. Enlargement of the thyroid gland may precede the other symptoms by years.

4. The skin shows diminished resistance to the electrical current (Vigoureaux), vitiligo, pigment spots, urticaria, a bronze coloration of the skin, redness, increased perspiration, loss of hair, and œdema of the lower half of the body.

5. Increase in the number of respirations, and cough; diminished distension of the chest after respiration, painless diarrhœa without a demonstrable cause, vomiting, boulimia, icterus, atony of the intestines and amenorrhœa.

6. Fever is observed in all stages of the disease; it may be ephemeral, remittent or intermittent; anæmia, and emaciation may be present.

7. The nervous symptoms are tremor, paraplegia, cramps, muscular atrophy, and disturbances of the mind.

8. The disease may be complicated with epilepsy, hysteria, paralysis agitans, glycosuria, polyuria, tabes, myxœdema, or syringomyelia.

9. Regarding the frequency of the individual symptoms, palpitation of the heart and swelling of the thyroid gland are never absent; pallor, emaciation, tremor, Stellwag's sign, and increased moisture of the skin are almost never absent; Graefe's sign, insomnia, and sensation of heat are frequent; pigmentation of the skin, diarrhœa, vomiting, insufficiency of convergence, and increase in the number of respirations, are often present. The disease is more frequently observed in females in the middle period of life. Etiologically, a neuropathic disposition is of the greatest importance; then follows rheumatism, influenza, climatic changes and traumatism. The course of the disease varies; remissions are frequent and cures questionable.

10. Pathological anatomy has disproven disease of the sympathetic as a cause of the affection. Superficial hemorrhages in the floor of the fourth ventricle have been observed in a few instances; there has also been observed enlargement of the thymus and lymph glands.

11. Therapeutically, besides such remedies as iron, arsenic, belladonna, bromide, etc., electricity, applications of water, and extirpation of the thyroid gland may be mentioned. Regarding the latter, Lemke says, "that patients with exophthalmic goitre belong not to the physician but to the surgeon." Möbius attributes the disease to a primary affection of the thyroid gland of toxic origin.

Medical Events.

Chloroform discovered by Guthrie of New York, 1831.

Pasteur's experiments in the line of germ culture, 1870-90.

THE LIBRARY TABLE.

Manual of Bacteriology. By George M. Sternberg, M. D., Deputy Surgeon-General, U. S. Army; Director of the Hoagland Laboratory, Brooklyn, N. Y., etc. Pp. 886. William Wood & Co., N. Y.

The appearance of a masterly work on bacteriology from the pen of an eminent American scientist will be greeted with delight by all American students and physicians. This work comprises both manual and text book in which can be found a carefully written description of about four hundred species of bacteria, and a detailed account of the technique necessary in bacteriological investigations. The work, as would be expected, is largely a compilation, but it brings into accessible form the best results of bacteriological research that have been obtained especially by European investigators. Perhaps the severest criticism that can be made on this work is the omission of a reference to a large amount of excellent work that has been done in the various laboratories in America.

The subject matter is divided into four parts: The first part treats of the history, classification and morphology of bacteria together with the technique. The methods given are well selected and reasonably condensed. This part includes also a chapter on experiments with animals,and one on photographing bacteria. The second part contains thirteen chapters on general biological characters of bacteria, including an account of the action of antiseptics and gemicides. This chapter contains many valuable facts and is of special interest to physicians on account of its discussions of the ptomaines toxalbumins, etc. The third and fourth parts are devoted to pathogenic and saprophytic bacteria respectively. The descriptions and illustrations of the more important bacteria are quite elaborate, while the description of the non-pathogenic and partially described pathogenic forms are given in small type thus adding data while saving space. The bibliography is extensive and arranged under appropriate headings. Although the book is rather large it is as small as the subject would permit. If more could have been added with profit nothing could have been admitted without injury. The work deserves a careful perusal by all who are interested in bacteriology, hygiene and medicine.

Text Book of Nervous Diseases. By Charles L. Dana, A. M., M. D. With 210 illustrations. Pp. 524. New York: William Wood & Co., 1892.

The work before us is one well worthy of commendation, and as far as its limits will permit, represents in a condensed form the state of our knowledge of Diseases of the Nervous System. Sufficient space is devoted to the Anatomy and Physiology of the nervous system to make the information serviceable in the consideration of its various diseases.

The work is divided into five parts. Part I., which is subdivided into five chapters, gives a general description of the nervous system, its anatomy and diseases, including diagnosis and methods of examination, treatment, hygiene, etc.

Part II. gives the anatomy and diseases of the Cranial Nerves. Considerable care has been taken to present a clear general view of the diseases of the Optic Nerve and Centers, as well as the motor nerves of the eye. It is an encouraging sign of the times that books on nervous diseases, intended for the student and general practitioner, embrace fuller descriptions of the diseases of the nervous apparatus of the eye and its adnexa, than the older writers gave. The important part which anomalies of refraction, accommodation and ocular muscular equilibrium play in the causation of certain reflex nervous disorders is being more fully recognized, and it is pleasing to find in the present work so large an amount of intelligible and useful information upon this branch of the subject. The purely optical considerations are very properly left for special treatises. In our opinion the study of the eye and its diseases should not be entirely relegated to the ophthalmologist. As the standard of medical education is raised, we hope to find the general practitioner as well acquainted with the eye and the ophthalmoscope, as he is with the chest and the stethoscope. The ophthalmoscope in modern medicine is indispensable for purposes of diagnosis. How often the indications of cerebral and other diseases, previously unsuspected, have been revealed by an ophthalmoscopic examination of the fundus oculi.

Parts III. and IV. are devoted to the anatomy and diseases of the spinal cord and brain, and Part V. treats of functional nervous diseases.

It is evident that no pains have been spared to make a general knowledge of the subject of neurology as easy of acquirement as possible, and to this end many useful tables are scattered throughout the work. The author's style is smooth and clear. The printing is well executed. The 210 illustrations, some of which are colored, help greatly to elucidate the text.

Physiology. By Frederick A. Manning, M. D., Attending Surgeon, Manhattan Hospital, N. Y. Students Quiz Series. Series edited by Bern B. Gallaudet, M. D., Demonstrator of Anatomy, College of Physicians and Surgeons, New York; Visiting Surgeon Bellevue Hospital, New York. Philadelphia: Lea Bros. & Co. Price $1.00.

Of necessity, a quiz compend must follow beaten paths, and the volume under consideration is no exception to the rule. It is uniform with the other volumes of the series and arranged in the form of question and answer. In common with all such works it is useful only as a means of refreshing the

memory—as a text book it is worthless. The author claims no originality, having drawn on the works of Dalton, Foster and others. In an appendix, a table of the development of the embryo, modified from Gray's anatomy; a concise description of the chemical tests used in physiological analysis, and a comparison between the metric and English systems of measurement are arranged in such a way as to simplify the student's work.

CURRENT LITERATURE REVIEWED.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY FOR FEBRUARY

contains an article by Dr. W. A. Briggs on the

Septic Origin and Antiseptic Treatment of Chronic Endometritis.

The causes of the disease are divided by the author into two divisions, active and passive. Besides infection no other active cause exists, all others—traumatism during abortion or parturition, the recumbent position during child bed, etc.—being passive. In the treatment the strictest antiseptic rules are to be enforced, even to the interdiction of sexual relations which may be a possible source of infection. Antiseptic douches are to be used twice daily, the author preferring to alternate the bichloride of mercury solution with a creolin solution on account of the danger of mercurial poisoning. The author is a firm believer in the efficacy of intra-uterine injections, using a solution of iodine and camphor in creosote. This, he thinks, is less apt to cause uterine colic than tincture of iodine, though he acknowledges that pain occasionally follows its use. Electricity he also considers a valuable agent in the treatment of endometritis, using the combined Faradic and Galvanic current when the uterine cavity is enlarged and the muscle flabby. In hypertrophic and hemorrhagic endometritis he advises the irrigating curette. Displacements, by causing stagnation of the circulation, aggravate the disease and should be corrected. Should the support of a tampon be necessary, he employs cotton soaked in glycerole of tannin.

Dr. O. B. Will in a paper on

Conservatism versus Radicalism in the Treatment of some Forms of Pelvic Diseases in women,

presents the non-operative side of the question. He justly attacks the men operating on any and the slightest indications, but at times the article becomes radical in its conservatism. "Diagnostic skill," he says, "is the first requirement and may be gained, in the majority of instances, without the assistance of ante-mortem or post-mortem dissection." Yet, he describes a case where he performed a laparotomy and ruptured a thin cyst of the ovary in a woman who had been treated for neuralgia of the ovary. Where did his diagnostic skill come from?—probably previous sections. Electricity is given a front rank in the treatment of pelvic troubles and he departs from the advice of Apostoli to withhold the electrode in the presence of pus, for he says "If after half a dozen *seances* there is developed no constantly increasing improvement—as evinced in lessened pain, tenderness and general irritability—I conclude upon further investigation into the probability of existing suppuration." Should not his first requirement, diagnostic skill, have been exercised earlier—before the application of an agent which all agree is most potent for harm in just this condition? Pyosalpinx is cured by catheterization of the tube and the injection of peroxide of hydrogen. "Daily or alternate-day applications of this character will soon put the parts in a healthy condition, pus or no pus." Should, however, both ends of the tube be closed and its walls distended with pus, then laparotomy is the only relief at the present time. As an example of conservatism "glued fast" the paper is an excellent one.

Dr. E. W. Cushing reports

Some rare forms of Myomata

removed by him. In one instance the ureters were found drawn up on the sides of the tumor. During the operation one ureter was cut, but the reporter was enabled to unite the severed ends by fine silk sutures. A urinary fistula resulted which promptly closed. The report is illustrated by excellent photographs of the tumors removed

Dr. Charles P. Noble contributes an article on "Vaginal Hysterectomy for Cancer," with report of four cases, which has already appeared in abstract on page 147 of THE MEDICAL AND SURGICAL REPORTER.

In the department of Pædiatry is an exhaustive paper on "The Diagnosis of the Meningitic Form of Enteric Fever in Children" by Dr. Georges Georgevitch, translated by Dr. Charles Greene Cumston. Typhoid fever in children is discussed and the similarity between tubercular meningitis and typhoid fever with pronounced brain symptoms pointed out. The differential diagnosis is considered and cases reported illustrating the various points under discussion.

THE MEDICAL BULLETIN

For February contains an article by Dr. John V. Shoemaker on

The Therapeutical Applications of Cocillana.

The chief use of the drug is in diseases of the respiratory tract, chiefly bronchitis, as it stimulates the capillary circulation of the bronchial mucous membrane, thus relieving inflammatory congestion. Cocillana may be administered in the form of the tincture or

fluid extract; though the author prefers the fluid extract, in doses of ten to twenty minims, combined with syrup. The paper includes the report of cases of bronchitis, influenza, hay fever and tuberculosis which were cured or relieved by the use of the drug.

Dr. John B. Brooke contributes a paper on

The Internal Use of Aristol

which he thinks saved the life of an infant suffering from entero-colitis. He administered the drug in ½ grain doses every two hours, combined with Dover's powder and sugar of milk. Since using it in the above case, which is reported in full in the paper, he has employed it with marked benefit in typhoid fever, dysentery and simple diarrhœa. He has not met with a case where the stomach would not tolerate it and advises its use especially where there is a muco-purulent discharge.

Dr. Edward C. Mann discusses the "Clinical Observation of Diseases of the Brain and Nervous System" in an article taken from the advance sheets of his work on Medical Jurisprudence. The question of localization of lesions of the brain and spinal cord is fully entered into,and the value of the ophthalmoscope in the diagnosis of diseases of the nervous system pointed out. The paper will be continued in the next issue of the journal.

Dr. J. Y. Hoffman reports a case of "Congenital Obstruction of the Bowels" where the post mortem revealed "an obstruction in the intestine about twenty-five inches from the pyloric orifice of the stomach, completely occluding the intestine. The mass was of a greenish blue color, of semi-solid consistency, adhesive in character." The intestine below was normal but had never been distended. A number of these masses were found but none occluded the intestine or were as firm in consistency as the first.

This number concludes with a clinical lecture by Dr. E. E. Montgomery on "Enucleation of Fibroids; Fibroid Tumors; Plastic Operation on the Pelvic floor; Vaginal Hysterectomy."

THE THERAPUTIC GAZETTE.

The February number contains seven original communications. "The Treatment of Acute Laryngo-Tracheitis" by Dr. Zeiss; "Salicylates in the Treatment of Pleurisy with Effusion" by Dr. Dock; "The Treatment of Incomplete Abortion" by Dr. Davis, are the more prominent articles. Dr. Kyle in a paper on

Resterilized Sponges, with Bacteriological Investigation,

states that the question of what is the best sponge to use in surgical operations still remains unsettled, some surgeons preferring the sponge, others the bichloride gauze. The sponges used in making this examination had been used in a septic case. They were resterilized by soaking twenty-four hours in bicarbonate of sodium solution, and then placed in carbolic acid solution (strength five per cent.) for one week. Some of the sponges were large and flat—elephant-ear sponges—while the others were thick and firm in the centre. Tubes were inoculated from each by taking from the outer layer of the sponge a small portion and placing this in the agar-agar tube; then cutting the sponge open, a small portion was taken from the centre.

The flat thin sponges showed no growth. With the thick sponges the experiment from the surface gave negative results; but from the thick, firm centers—from eight different inoculations, in from two to five days, at a temperature of 80° F.,—each showed marked growths. Stains made from these tubes showed numerous bacteria. By the process of isolation the micro-organisms of suppuration were found. The sponges were left in the carbolic acid solution for six weeks. Then inoculations made as before, gave practically the same results. The thick sponges were subjected to pressure while in the fluid, and inoculations made showed no change as to results. In making these experiments the same precautions were taken as would be necessary in any antiseptic or aseptic operation. The inoculating needles, forceps, scissors, etc., being sterilized in a steam sterilizer, and the experimenter's hands being prepared by soap, water and brush,—special attention being given to the cleansing of the nails—then washing in bichloride solution (1 to 1000). In each case satisfactory check experiments were made, which proved that the infection did not come from any want of antiseptic precautions during the experiments.

THE SEI-I-KWAI MEDICAL JOURNAL

Is edited and published by the Sei-i-Kwai, or Society for the Advancement of Medical Science in Japan. The December issue concontains three original articles in English and four in Japanese.

"Report on the Treatment of Ovarian Cysts" by Dr. Yoshida; "Sketch of the Process of Manufacturing Camphor in Japan;" "Immunity from Leprosy of the fifth generation and Non-Contagion" by Dr. Ashmead are the English articles.

It is interesting to learn from Dr. Ashmead's paper on

Immunity from Leprosy of the Fifth Generation

that there is a fact which bears very directly and very strongly upon the subject of the non-contagiousness of Leprosy. It is recognized by all Oriental leprologists that every child of a leper has an inheritance of the disease but diminished, and that after the fourth generation, if no healthy blood intervenes, the disease is entirely extinguished. There is about these matters a very interesting law in China and consequently in Japan, the latter being, in spite of its western civilization endeavors, much more submissive to Chinese traditions than to European ideas.

"No marriage with children of leprous parents is allowed. If leprosy appears in a family formerly clean, all betrothals and contracts of marriage previously entered into, are rescinded as a matter of course. Only when the betrothed or married persons suffer of the same degree and type of leprosy, for

instance, both of the fourth degree of generation, the alliance stands. Only equal degrees of age of the morbid cases are allowed to connect themselves by marriage. A leper of the fourth generation, even if he no longer shows any external marks of the disease, can only marry a woman of the same degree of age of the disease: their offspring is free from leprosy and no longer forbidden human intercourse."

Here we have then a perfect immunity acquired in four generations, and the fifth generation restores the health of the race. There is certainly a connection between this extinction of the disease and the present immunity of Europe when that part of the world had been a prey to leprosy during several centuries of the middle ages. Evidently in the West, simple isolation has unconsciously accomplished, in the lapse of time, what a rational legislation tries to bring about in the East. The legislation has probably preserved the populations of China, and of the East in general, from entire destruction. I do not mean to say that the rule is always and carefully adhered to, because, in that case, the disease would be extinct now: but the rule is sufficiently known, and sufficiently adhered to, to make its salutary consequences felt.

THE MEDICAL REPORTER.

The January issue of *The Medical Reporter of Calcutta* contains an interesting article on

The Treatment of Tuberculosis with Tuberculocidin.

Speaking of the preparation of Tuberculocidin Prof. Klebs states that it can be prepared in various ways, but it is a common feature of all methods that the substance precipitated from crude Tuberculin by platinum chloride and so-called alkaloidal re-agents, contains the injurious substances of the remedy, while the albumose, remaining under this treatment in solution, which can be thrown down and purified by alcohol, forms the remedial agent of the crude Tuberculin. This preparation brings about no disturbance in the evolution of heat by healthy animals, and is altogether free from the action on the heart which is peculiar to crude Tuberculin, as well as to the substances thrown down from it by platinic and other salts.

All these injurious effects, to which in human beings a long list of direct lesions of the nervous system have been added, are avoided by the application of the purified remedial albumose "Alexin" or Tuberculocidin. Very large doses of the latter, up to one-third grain *pro die* are of course followed by disturbances in many patients, specially manifested in a more or less troublesome feeling of weariness as well as in further emaciation in the earlier stages of the treatment; this, however, in favorable cases is made up later, and indeed, often gives place to a very evident gain of weight.

From this therefore it is seen, that Tuberculocidin though free from the dangerous by-effects of crude Tuberculin, can by no means be regarded as an indifferent substance. Further it is also clear that it is not merely a diluted Tuberculin: Tuberculocidin constitutes about 2½ per cent. of the crude Tuberculin, and if it were only a dilution of the latter, volumes of the two bearing the respective proportions to one another of 40: 1 should produce the same action. As the quantity of 1½ grain Tuberculocidin—attained after a few doses in tuberculous human beings—produces no fever, whilst crude Tuberculin in these subjects, in a dose of $\frac{1}{25}$ grain often brings about a very considerable rise of temperature as Dr. Robert Koch, among others, has established by alternate injection of the two substances, is clear that *the action of Tuberculocidin and Tuberculin is quite distinct.*

The article goes on to consider "The action upon the Tubercle Bacillus," etc., to be concluded in another issue.

Dr. Banerjee has a paper on "Ophiology or a description of the Snakes of India." "Topical Dysentery" by Dr. Day, and "Unique cases of Paresis" by Dr. Shah, of Junagadh, conclude this number.

THE PRACTITIONER.

The January issue contains an interesting paper by Dr. Wilks, on "The Value of Drugs." He calls attention to the uses of Iodide of Potassium, the Bromide of Potassium; Exophthalmic goitre, or Graves' disease, cured by Belladonna; the value of Arsenic in Idiopathic Anæmia, the care of Tuberculosis peritonitis and Dysentery and Chronic Diarrhœa. This paper contains no novelties; it is merely an expression by one, who has had a long experience, of his conviction of the value of drugs.

Dr. Duckworth has an article "On Some Matters Relating to Dietary for the Sick."

"Gout of the Intestines; its Pathology and Treatment" is offered by Dr. Haig. A continued article "Passive Congestion of the Lungs from Heart Failure" by Dr. Morison is concluded in this number.

"The Treatment of Myxodema" by Dr. McCall Anderson will be found quite instructive. The principle treatment consisted of the administration by the mouth of thyroid juice. Eighty minims (two-thirds of extract of one thyroid) was used. A fourth part of this was given on four consecutive days after which an interval of three days elapsed before any more was administered. Five days after the treatment was commenced showed marked improvement which continued on uninterrupted until at the end of four weeks, when the patient expressed the opinion that she was quite well. A set of photographs illustrating in a striking manner the change in the appearance of the patient accompany the article.

OBSTETRICS.

Measuring the Pelvic Outlet before Labour.

Tarnier (*Jour. des Sages-Femmes*, October 16th, 1892) recently gave a clinical demonstration respecting a case of dorso-lumbar kyphosis. The patient was hump-backed, the prominence being low down; in such cases the pelvis is nearly always transversely contracted, forming the funnel-shaped pelvis. In this patient the pelvic inlet was enlarged; measurement was very easy. On the other hand, the outlet was, as usual, very difficult to measure. No compass or pelvimeter gives precisely the distance between the tuberosities of the ischium. The best plan is to place the patient on her face with the nates raised. The obstetrician places his hands outside the tuberosities, the thumbs being pressed against those prominences. An assistant then measures the distance between the thumb-nails. It is normally $2\frac{3}{4}$ inches. In Tarnier's patient it was but 2 inches. With the aid of forceps labour was terminated without difficulty, and mother and child fared well.—*Br. Med. Jour.*

GYNECOLOGY.

The Frequency of Local Symptoms of Uterine Displacement.

Dr. Herman gave the results of some 407 observations made by him with the object of determining the relative frequency of the local symptoms associated with retroflexion or retroversion of the uterus. He discussed the two displacements together, no great importance attaching, in his opinion, to the distinction between them.

He found that *chronic pain* of some kind was present in nine-tenths of cases of backward displacement of the uterus. The most frequent seat of pain was the back, generally the sacral region. Next most often came sensations of descent, and uni-lateral pains, mostly in the ovarian region, cases of left-sided pain outnumbering those of right-sided pain in the proportion of three to one. In a short proportion lower abdominal pain was the chief complaint, and in a very small minority trouble in locomotion was the prominent symptom.

Pain in defecation was present in less than half the cases. In the majority of the cases in which it was present it was accounted for either by constipation or by morbid conditions of the rectum. The author estimates the proportion of cases of backward displacement of the uterus in which the displacement is the sole cause of painful defæcation at about one in nine.

Backward displacement of the uterus had no appreciable effect as a cause of *painful micturition*; but *bladder irritation* due solely to the displacement was present in about one case in five.

Leucorrhœa was not commoner in cases of backward displacement of the uterus than other patients.

Dyspareunia was present in at least one-sixth, and probably in a larger number; absent in at least one-seventh.—*Med. Weekly, Paris.*

NEWS AND MISCELLANY.

Another Four Year School.

The Woman's Medical College of Pennsylvania now requires all new matriculates to take four annual courses of graded instruction before being eligible for graduation. This is an evidence of the rapid progress made by the movement to elevate the standard of medical education.

American Surgical Association.

The preliminary programme for the meeting to be held at Buffalo, N. Y., May 30, 31, and June 1, 1893, is as follows:

President's Address.

1. The Modern Treatment of Compound Fractures. By Dr. Nicholas Senn, Chicago. Discussion by Drs. Roswell Park and F. S. Dennis.

2. Hypertrophies and Degenerations of Cicatrices and Cicatricial Tissue. By Dr. J. Collins Warren, Boston. Discussion by Drs. C. H. Mastin, G. R. Fowler and W. H. Carmalt.

3. Surgery of the Gall Bladder. By Dr. M. H. Richardson, Boston. Discussion by Drs. J. Ewing Mears, A. Vander Veer, W. H. Carmalt, and Theo. A. McGraw.

4. Surgery of the Rectum. By Dr. A. G. Gerster, New York. Discussion by Drs. L. S. Pilcher, H. H. Mudd, and L. McLane Tiffany.

5. Surgical Treatment of Cervical, Thoracic and Abdominal Aneurism. By Dr. C. B. Nancrede, Ann Arbor. Discussion.

6. Surgery of the Prostrate. By Dr. J. William White, Philadelphia. Discussion by Drs. Hunter McGuire, T. F. Hewitt, R. F. Weir, and F. H. Gerrish.

7. Treatment of Carbuncle. By Dr. F. Lange, New York. Discussion by Drs. Robert Abbe, J. B. Roberts, and J. S. Wight.

In addition to the above specially selected subjects, the following papers have been offered:

1. Unreduced Dislocations of the Astragalus. By Dr. Stephen Smith, New York.

Fellows who propose to present volunteer papers are requested to send to either of the undersigned the titles of their proposed papers as soon as possible, in order that they may be properly classified and arranged for the final programme.

Fellows are also requested to notify the Chairman of the Committee whether they will take part in the discussion upon any of the special subjects given in the above list.

Nicholas Senn, President, J. R. Weist, Secretary, J. Ewing Mears, Recorder, F. S. Dennis, John S. Billings, Business Committee.

PHENACETINE-BAYER

THE TESTIMONY of physicians accords to Phenacetine the first place in the list of modorn Antipyretics and Analgesics. It acts promptly and effectively within the limit of safe dosage. It lowers Fever, quiets Pain, and induces gentle Diaphoresis.

INDICATED in Pneumonia, Rheumatism, Neuralgia, La Grippe, Hemicrania, and all Febrile Conditions.

Phenacet ne is supplied in ounces, also in Tablets and Pills, alone and combined with Salop hon, Salol, etc.

SULFONAL-BAYER

ALL PRACTITIONER's speak well of Sulfonal. Its action is purely Hypnotic. In small doses it is a Sedative. It is safe and reliable; it gives rise to no sequelæ and causes no drug habit. It must be given As Directed.

INDICATED in the Insomnias and the Neuroses. In painful insomnia it may be combined with Phenacetine.

Sulfonal is supplied in Ounces, Tablets and Pills Also in Tablets (2 sizes) combined with Phenacetine.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Vaccine Matter.

For the accommodation of our Subscribers, we will supply both Bovine and Humanized Vaccine Virus.

Guaranteed to be fresh and in every respect first-class.

PRICES:

Bovine Crusts,	**$1.50 each.**
Bovine Points or Quills,	**1.00 a dozen.**
Humanized Crusts,	**1.00, small.**
Humanized Crusts,	**2.00, large.**

Nothing less than half dozen sold at these prices.

The Humanized Crusts are warranted to be from typical cases, and in every instance from healthy children, with unquestionable family histories.

Please accompany the Order with the Money.

ORIGINAL ARTICLES.

THE PREVENTABLE DEATHS OF CHILD BIRTH.*

HERBERT TERRY, M. D., Providence, R. I.†

This subject was brought to my mind by the death, in another State, of a lady 23 years old, an only child, married but little more than a year, and under circumstances which I think you will all agree could be the result only of gross neglect on the part of the physician in charge. When this lady was seven and one-half months pregnant, I learned through a mutual friend that the family were greatly worried because she was bloated, especially in the face and hands. The confinement was expected about January 1, and since the last meeting of this Association, I have learned of her death.

In this little state of Rhode Island, during 1891 (the last report to which I had access) thirty-two women lost their lives in child birth. Though not exactly *apropos*, I cannot help quoting Dr. Helen W. Bissell in the *Northwestern Lancet*. She says: "Some may argue that accidents occur only once in fifty or one hundred times, but I think if one in fifty or one hundred passenger trains ran off the track there would be a loud call for a somewhat different management."

The preventable deaths in child-birth I hold to be from post-partum hemorrhage, puerperal eclampsia, and puerperal fever. Deaths from exhaustion are not occurring in recent years with the universal knowledge of the use of forceps and other means for hastening delivery in the interests of the mother. Neither do I wish to include deaths from placenta prævia among those preventable, though probably in no class of abnormal cases of childbirth does so much depend on the judgment and experience of the attendant as in those in which the placenta is prævia. The treatment, however, is no more preventive of death than is tying an artery that is wounded. So might craniotomy, Cæsarean section or symphsiotomy be likened to an amputation for malignant disease, though the dangers from these formidable operations might be avoided by the frequent use of the pelvimeter.

The almost universal cause of post-partum hemorrhage is a relaxed state of the uterus. After the child is born it is usual for the uterus to remain at rest for a time (perhaps twenty minutes) when contractions for the purpose of separating and expelling the placenta begin. As the placenta is separated from the uterine wall, the blood vessels are closed by the peculiar arrangement of the muscles and blood vessels. The time elapsing between the birth of the child and the birth of the placenta may be diminished by stimulating the uterus to contract by rubbing it when contraction occurs, hastening the expulsion of the placenta by compression after the manner of Credé. While too early separation of the placenta either by compressing the uterus or, what is worse, pulling on the cord, is usually promptly followed by a uterine contraction that

*Read before the Providence Medical Association, Jan. 1, 1893.

†Visiting Physician to the Providence Lying-in Hospital.

closes the blood vessels, yet the saving of time is at too much risk of leaving the vessels open. After the placenta is delivered the uterus should be watched and firm contraction insured by stimulating it on the slightest sign of relaxation by cold or rubbing. This is of value to prevent post-partum hemorrhage, and it will be appreciated by your patient as a preventative of after-pains. If, after twenty minutes to half an hour, the uterus remains well contracted and the pulse has diminished naturally in frequency, then, and not until then, may the patient be left. Of course, such accidental causes of post-partum hemorrhage as ruptured varicose veins in the vagina, lacerated cervix and the like need not be considered, though it is well to bear in mind that a full bladder may interfere with the contraction of the uterus after, as well as before, labor is completed.

In all the records to which I have had access, of autopsies performed on women dying of puerperal eclampsia, kidney lesions have been found. If puerperal eclampsia has occurred without some previous symptoms of renal incompetence, it must have been very rarely. Albuminuria, abnormally low specific gravity, *with* or *without* a diminished secretion of urine, are the principal symptoms referable to the urine. Albuminuria may be transient or, I think very likely, absent as it frequently is in some of the chronic forms of Bright's disease. Of the other symptoms of renal incompetence the prominent are vomiting, œdema, headache, disordered vision, vertigo, restlessness, sleeplessness, weariness and mental disorders, especially mania. Any one of these should lead to a careful consideration of the patient's condition. I have learned by experience that a severe trace of albumin, even with some œdema of the feet and legs, may be disregarded. I have also learned that a considerable amount of albumin, even though the patient shows no other sign of illness and is in the best of spirits, it is a danger signal *not* to be disregarded. It is the duty of every one of us to examine the urine of those whom we expect to attend in confinement, with sufficient frequency to be certain that the urine is normal, and to request the patient or some member of the family to report at once the occurrence of any of the symptoms enunciated above.

Omitting any theories, it is without doubt the existence of pregnancy that determines the kidney lesion, and after delivery in the majority of cases, the kidneys regain their functions. It is a recognized fact too, that the most important factor in the successful treatment of the convulsions, when they do occur, is the emptying of the uterus. It follows from these two propositions that the most successful preventative treatment of puerperal eclampsia lies in abortion or premature delivery.

The child's existence, however, must be taken into consideration, and abortion or premature delivery must be recommended with some qualification. If the child is viable you have no more right to subject the mother to the risks of convulsions or irrecoverable renal disease by allowing the pregnancy to continue, than you have to subject the child to the risks of being prematurely born. If, however, the child has not reached a viable age, then an abortion should or should not be performed, according to the length of time pregnancy has already existed. If the child has already arrived nearly to a viable age, i. e., if pregnancy has existed six and a-half or seven months, attempts should be made to carry the mother successfully along by means of diaphoretics, diuretics, cathartics and tonics until the child is viable, when premature delivery should be accomplished. If, however, renal disease is discovered during the early months of pregnancy, any attempt to continue the pregnancy can result only in disaster. If convulsions do not occur, a disease which cannot be recovered from is the result. Fortunately nature solves the difficulty in the majority of cases by a spontaneous miscarriage, and we should follow her limits by inducing abortion under the same circumstances.

The last class of cases considered covers, of course, those in which pregnancy supervenes on pre-existing Bright's disease. Although hardly within the province of this paper after what I have written, I cannot but add that premature labor should not be induced without preparing the patient for it by free watery catharsis, lest we should bring about the convulsions we wish to avoid.

The greatest number of deaths occuring in child-birth are from puerperal fever, and yet these above all others, are with most certainty prevented. Puer-

peral fever is every time sepsis and prevention is asepsis. This is not *probably* so, it is a positive fact. It is not uncommon to hear practitioners, after years of experience in midwifery, claim with a boastfulness that is truly childlike, that they have never used antiseptics in childbirth and yet have never had a case of child-bed fever. So do some thieves escape the police for years. But unlike the doctor the thief takes the chances himself. That I have a right to make this assertion in regard to aseptic midwifery as strong as I have, is shown by the report of the Boston Lying-in Hospital for 1891. Out of 1270 women delivered, there were but four deaths. One of these deaths was from cancer; one from phthisis; a third out of the four from scarlet fever, and in all death took place after a safe delivery. The fourth death was from the vomiting of pregnancy, and the exhaustion was so extreme when the patient was brought to the hospital that nothing could be done to save her life. If we except this last, as we must, there was not one death out of the 1270 women attended, that was attributable to child-birth. And this in a hospital where, before our knowledge of the nature of asepsis, it was dangerous for a patient to be confined. During my own term of service as house-officer in 1879, when we washed our hands *after* an examination and not before it, and lubricated the examining finger with vaseline from the same jar that was moved from one patient to another as required, out of ninety-eight women delivered, five died and eleven had puerperal fever. What a showing that is by the side of the report from the same hospital for 1891.

My own practice now is, in the first place, to make as few examinations as possible; most of the diagnosis is made from external palpation, the length of time labor has been in progress, and the character of the pains. It has been advocated even to omit vaginal examinations altogether unless interference is probably necessary. Before the patient is approached, the hands and arms are thoroughly washed in soap and water and scrubbed over and over again with a nail brush. Then they are scrubbed over and over again in a 1-1000 solution of corrosive sublimate. The patient's genitals are carefully washed by the nurse. Any instrument to be used is sterilized in boiling water and kept in a solution of carbolic acid. Hands and instruments are lubricated with "bichloride soap" rendered soluble by a 1-1000th corrosive sublimate solution.

Of the after-treatment I can only say it is carried on as strictly as possible in the same lines of asepsis. I believe that it is a result of this care that I rarely see "milk fever," and have never, so far, to regret the occurrence of a case of child-bed fever, either in my private or hospital practice. This paper is not intended to be explanative, and, of course, it covers only what everybody knows, but the number of deaths from child-birth in Rhode Island, which have been acknowledged to be due to preventable causes, shows very plainly, that greater care might,—in fact, should,—be taken.

The Armour Institute.

The erection of this building by Mr. Philip D. Armour has been going on for a year, but the purpose of the building was kept "dark" until Mr. Armour left for Europe recently. He gives this building and an endowment of $1,400,000, but that does not include the fittings, which are to be put in at Mr. Armour's expense. The building is one of five floors. On the second are the chemical laboratory, the chemical lecture room, the physical laboratory, the physical apparatus room, the physical lecture room, and electrical rooms. The third floor will be used by students in freehand drawing, mechanical and architectural drawing, and in commerce and business.

The fourth floor is devoted to the domestic sciences, there being departments of cooking, dressmaking, millinery, and kindred studies. At one end of the fifth floor are the gymnasium and technical museum. The faculty of the institute will be of the highest standing, and it is Mr. Armour's desire that students may have opportunities to be prepared for the higher universities, or practical work in any field or mechanical or scientific labor. Every possible convenience for scientific research and experiments will be provided. The institute is not located in a fashionable portion of the city, and Mr. Armour's idea in placing it where he has, is said to be to put the institute among those whom it will most benefit.—*Ex.*

CLINICAL LECTURES.

SARCOMA: ARTHRITIS DEFORMANS: CICATRIX FOLLOWING BURN: MORBUS COXARIUS.*

ROSWELL PARK, A. M., M. D.

SARCOMA.

This patient is a man, aged thirty-one, who presents a tumor in the region of the groin. Four weeks ago he received a blow in this place from a barrel. Previously he was perfectly well and was not aware of any swelling in the groin until after the injury.

The inguinal tumor is evidently composed of lymph nodes and we might jump to the conclusion that we have here buboes, and begin to search for evidences of past or present venereal disease. But of this we get neither indication nor history. The next hypothesis would, perhaps, be of tubercular involvement of the nodes. But there is nothing to verify this diagnosis. We have to differentiate, I think, between tubercular and malignant disease. There is a history of injury which has a little bearing on the case, but not very much since malignant disease is known to develop rapidly after an injury, and it has been known to occur with just the same rapidity without any traumatism. It is possible to have a tubercular infection also following an injury. To aid in the diagnosis I call your attention now to another feature, namely, a large mass in the pelvis above Poupart's ligament and dipping down into the iliac fossa. Yesterday, on rectal examination, it was easy to make out a mass with which I could get almost a ballottement. Considering the presence of the large mass in the pelvis with the external lymphatic swelling, the diagnosis becomes almost certain, that we have to deal with a malignant condition, and probably a sarcoma. Of course, it might be a carcinoma, but this mass, so far as I can learn, arose in tissues which are not supposed to have epithelium, and the patient is rather too young for carcinoma.

The patient has not suffered much pain; he has failed quite rapidly; there has been no temperature development such as would be expected with tuberculosis, and so, partly from the absence of that which we would look for in tubercular trouble, and partly from the presence of the large pelvic mass, which is larger than I have ever seen develop in the same length of time from tubercular infection, I have come to the diagnosis of sarcoma of the lymph-nodes and the lymph channels extending from the groin up into the pelvis.

The mass extends too deeply into the pelvis to justify any attempt at extirpation. If the trouble is going on as rapidly as the patient thinks, there must certainly be lymphatic involvement above the point at which I can detect it from the outside. While it would be perfectly possible to remove the mass in the groin and even to separate a large portion of the internal tumor, I should feel certain that I was leaving *in situ* the seeds of fresh trouble, and so I should not advise operation in this case.

I should advise the experimental use of arsenic iodide in doses as large as can be tolerated, commencing with four milligrams three times a day; then giving four doses a day and increasing the dose as much as possible. Or one may give Donovan's solution of the iodide of mercury with the iodide of arsenic. We should commence with doses of twenty drops three times daily, to be pushed to the physiological limit. I think it is certainly true that arsenic influences cell growth, and there are cases in the experience of every surgeon, of neoplasms whose growth has been rendered slower or checked by the internal administration of the drug. But I should regard it as miraculous if this case were cured—provided I am right in the diagnosis of sarcoma. All that I hope to do, therefore, is to check the growth of the tumor, cause the subsidence of a distressing symptom and prolong the patient's life.

*Buffalo General Hospital Surgical Clinic. Reported by A. L. Benedict, A. M., M. D.

ARTHRITIS DEFORMANS.

This patient is a man of fifty, who presents a very curious condition of the knee-joint. I shall not attempt to give you an exact diagnosis previous to the operation. I first saw him two years ago, a fact which I had forgotten till reminded by the patient. About eleven years ago he fell from a load of hay, striking with this leg and joint upon a pole which lay on the ground. In some way the joint was seriously injured. He has been lame and partially disabled ever since. The joint has been swollen and in its present condition for about two years. He says it is over two years since he himself noticed inside the knee-joint a movable body, not one of the little masses of detached cartilage which the Germans call "joint mice," but a good-sized body. There is certainly something of the kind in the joint cavity, as nearly as we can judge from the external sensations. There is a large amount of distension of the synovial sac; there is alteration in the shape of the bones, especially the upper end of the tibia, and there is more or less bony outgrowth from the margin of the head of the tibia. The knee is growing slowly worse instead of better, and I have advised the patient to have at least an exploratory operation performed, and then, if anything calls for further interference, to allow me to meet the indication.

Around many joints, as the result of injury, or even of the uric acid diathesis there are formed masses of new tissue, and alterations occur in their contour with the growth of exostoses so that the original appearance of the joint becomes totally changed. To these conditions in general has been applied the term *arthritis* (or *osteitis*) *deformans*, and, undoubtedly, in this case we have to deal with something of this character. The operation has for its purpose a better acquaintance with the internal conditions; the removal of whatever diseased or deformed tissue can be removed, and the improvement of the function of the joint. Incidentally we must try not to make matters worse than they are at present.

He has had just the preparation which every case of any importance has in my clinic. The area of operation is shaved and cleaned, a green-soap poultice is applied and the part enveloped in an antiseptic dressing for twenty-four hours before the operation. The knee is now scrubbed with a bichloride solution, and the adjoining parts are covered with towels moistened in the same solution. The hands of all of us who come in contact with the field of operation or the instruments and dressings, are thoroughly cleansed with soap and water, care being taken to keep the nails short and to brush vigorously around and under them.

We now add antisepsis to apparent cleanliness by dipping the hands into a potassium permanganate solution. Those of you who are near can smell the ozone which arises, and you can all see how the organic matter is blackened. The hands are then bleached in a solution of oxalic acid and hyposulphite of sodium.

When the knee is drawn up you notice the irregular bosselated appearance, some of the swelling being fluctuating and consisting of the distended joint-capsule, the rest being a bony outgrowth. Above the margin of the head of the tibia I feel a hard mass, and above this a movable body of whose adhesions to other tissues I can form no idea until it is exposed. The slow growth seems to be more of the nature of an exostosis than of a true osteoma. Malignancy, I think, we can exclude altogether. In exostosis there is some feeble suggestion of physiological function, a mark of distinction from an osteoma.

On making a longitudinal incision at the inner border of the patella I come upon the movable mass to which allusion has been made. It is very closely adherent to the surrounding tissues and I will dissect it out with the scissors while an assistant holds it with the tenaculum. The tissues about the joint are enormously thickened and I doubt if I have even yet entered the joint cavity proper. Above this mass I feel something large and hard, which proves to be the enlarged condyle of the femur. As I manipulate the leg you observe that there is considerable lateral play permitted by the disorganization of the ligaments. The external lateral ligament is particularly weak, for bringing the leg inward and then suddenly outward, there is a hammering sound as the bone surfaces come together. This is entirely abnormal, and must be due to the relaxation of the outer lateral support. I do not feel that any further interference is necessary after removing this mass and

trimming away some of the newly formed tissue. I will, therefore, close up the cavity that I have opened. There are no dead spaces left to require drainage. I am using the subcutaneous suture which leaves no cross-marks and makes only a linear scar. After applying the antiseptic dressing a well-padded posterior splint is bound on the limb and, later, the leg will be done up in plaster-of-Paris in order to give it prolonged rest.

CICATRIX FOLLOWING BURN.

This patient affords one of the best possible illustrations of the evil results of vicious cicatrization following a burn. About fifteen months ago he was burned about the face and arms by a coal-oil explosion. The burn was of the second degree, according to the simpler classification into three degrees which I think is preferable. The old French writers used to give a classification into seven degrees, which is almost like the seven degrees of grace, rather indefinite and hard to outline. Three degrees may be very clearly defined—(1) When the epidermis alone is burned; (2) When the epidermis is burned through to the subcutaneous tissue; (3) When the burn is very much more extensive.

Burns leave enormous surfaces which have to heal by a process of granulation and cicatrization, except that where little islets of epithelium are left undisturbed the cells may proliferate and help form a covering something like a true skin, but destitute of sudoriferous glands and hair follicles. When the epithelium has been entirely destroyed we can hope for nothing more than a cicatricial covering. As I have had to remind you often, the result of the inevitable contraction of cicatricial tissue is to produce more or less deformity. The very worst illustration of this which I ever encountered was in a boy who was brought to this clinic three years ago with a very extensive burn of the front of the neck which was almost dislocated by the drawing of the cicatricial tissue. Relative to the condition when I first saw him, the boy made a good recovery after a most extensive operation.

This case is not so bad, but there are cicatrices of the anterior region of the neck which draw the chin down. The same contraction has drawn down both shoulders so that one arm can scarcely be lifted from the side. The patient seeks relief and he has been told that the operation consists in substituting one scar for another, but allowing the more annoying cicatricial tissue to be cut away. I shall try to raise flaps of normal skin from contiguous regions and transplant them to the affected regions, leaving hinges to insure their blood-supply. This is a kind of plastic work which has often to be resorted to in cases of this sort. Two weeks ago we had here a case of a young woman who was also burned by coal-oil in about the same way as this patient. She had along the border of the jaw a very thick keloid scar which she considered a very serious disfigurement and which she wished to have removed. I accordingly dissected it out and put up a flap from the neck to cover the raw surface.

The scars here are not only bands of fibrous tissue but they have a livid red appearance and an irregularly raised or "napped" appearance which entitles them to be considered as in some degree keloid. Keloid is a peculiar kind of fibrous tissue which is stimulated to grow especially after such accidents as burns. Keloid tumors do occur spontaneously, as large hyperplastic growths of the fibrous tissue of the skin, quite similar to fibroids or even some fibro-sarcomata. The structure is not exactly the same, although it is similar. Such tissue as you see here is quite different from the smooth cicatrix which forms after the healing of ulcers. The tendency to the formation of keloid tissue is something that cannot be prevented. The more you cauterize it and try to keep it down, the more you will provoke its growth.

What annoys this man particularly is the presence of one or two strips of keloid tissue on the neck which bridle down the head. I shall remove these and substitute, as well as I can, skin flaps from the surrounding parts. In a case of this kind, it is well not to raise the patient's expectations too high. The cosmetic effect will not be ideal under the best of circumstances. Fortunately, this patient does not care about that element in the treatment. He wishes to be relieved of the limitation of movement caused by the keloid scars.

MORBUS COXARIUS.

As this boy sits on the table you notice the apparent shortening of the left leg. As he stands you will observe that he

stands on his toes and there is great displacement at the hip; as he lies on his back, with the knees raised and the thighs flexed on the trunk, when I attempt to bring his knee to the table the back is raised. There is a teetering, so to speak, of the knee and back, owing to the spasm of the psoas muscle which prevents motion at the hip. There is marked adduction, and in the endeavor to make the normal leg parallel with the adducted one, his body is drawn to one side. The adduction is due to spasm of the adductor muscles. I can hardly make any motion of the thigh without moving the pelvis. We can make out the actual shortening in one of two ways; either by measuring from the anterior spinous process of the ileum to the internal malleolus, or by bringing his knees up when, if the pelvis is horizontal, any shortening will be evident by the knee of the affected side being lower than the other. In this case the actual shortening is slight, the marked difference in the two legs being due to the adduction of the affected one. I can illustrate this to you by sitting before you with my feet drawn upon the round of the stool. While my body is at right angles to you and my feet pointing directly toward you, the knees are in the same plane parallel to the lateral plane of the body. But if I turn slightly, by adducting one thigh and abducting the other, then the knee of the adducted leg appears nearer the body and there is apparent shortening of that extremity.

There is no question but that this is a case of hip-joint disease in the second stage. The boy's parents are very poor and have not the means for buying an apparatus. I think it *might* be possible in such a case, given time and money and careful supervision, to treat the disease apparently successfully without operation. There being no sign of suppuration yet, although there must be a focus in the bone somewhere to produce the reflex symptoms, I believe that by first keeping the child in bed with weight and pulley applied to reduce the muscular spasm, and then by nourishing him freely and getting him out doors with a splint to keep the leg motionless, we could probably effect a cure by ankylosis. This would require at least a year's time and would entail a relatively great expense for a poor man, for the splint alone would cost at least thirty-five dollars. It would be a pity to start such a line of treatment and then find that the parents could not persist in it. Under the circumstances, therefore, I should recommend resection as being the quickest and cheapest means of cure, and I would not be averse to it at any time though now it is expedient rather than necessary. Ten years from now I believe the boy will be better off with the resected joint than he would be with the ankylosed hip-joint which could be obtained from the costly rest treatment. The upper end of the bone is not now enlarged, or I should recommend resection without regard to the features alluded to above. In fact, on general principles I believe that the results of exsection approach nearer to the ideal desideration than can be obtained in any other way, save in certain very favorable cases which are seen very early by competent men.

Dislocations.

Never attempt to reduce a dislocation of the humerus in an old person without first examining the state of the arteries to inspire you with caution and gentleness.

Never put a *booted* foot in the axilla to reduce a dislocation.

Always reduce by some other method if the rib are broken on the same side.

Remember that injuries to the elbow joint are often very difficult to diagnose, if much swelling co-exists; but:

Never give a positive opinion of an elbow joint until you have carefully examined the relations of the olecranon, internal and external condyles, and head of radius.

Remember that in dislocation at the elbow the joint becomes rapidly irreducible.

Never forget that a faulty diagnosis may cause loss of motion in the joint.

Never be ashamed to say you "do not know" until the swelling has subsided, and you are able to be certain of the character of the injury.

Do not forget that in dislocation of the carpal bones that the great point is to see that the motions of the fingers are early restored.—*Med. Era.*

COMMUNICATIONS.

CARDIAC STIMULATION IN PNEUMONIA*

JOHN A. LARRABEE, M. D., Louisville, Ky.

Pneumonia has probably been the subject of more medical literature than any other disease. When I graduated in medicine, I am quite certain that, of thirty-five thesis required of candidates for graduation, pneumonia constituted the subject for about twenty-five. I well remember the compliment paid me by the Faculty because I had chosen some other subject. I wrote my thesis for graduation on the subject "Hospital Gangrene," and I have many times thought what a relief it must have been to that dignified body—most of whom are numbered with the angelic doctors—to have a change of subject. I may add with pardonable pride that my thesis was made the subject of special mention.

Those puerile compositions were a tolerably fair reflection of the medical teachings of those days in which *idiopathic* inflammation was an acceptable term when illustrated by the stages "Calor," Dolor," "Rubor" et "Tumor." It is also true that there is no disease that more clearly marks the progress made in scientific medicine for the last twenty-five years, than this same trite subject, pneumonia. The auscultatory signs, the percussion note, the transmitted resonance, the hepatization and the stage of resolution were necessary to the elucidation of the phenomena supposed to be produced by a "bad cold." Cheesy deposits, the unabsorbed products of inflammation, were but different stages in the development of tubercle and the cause of the rapid consumption.

How little did we then dream that behind all this patient pathological study in which we have all craned our necks in the "dead house;" that, underneath all this crude tubercle and cheesy deposit there existed a wonderful world teeming with microscopic life, the light of which should make plain the darkness of that pathology.

Before the wonderful discoveries of Friedlander I taught the crisis of pneumonia was to me a most unaccountable phenomena, in that, without any visible improvement in the consolidated lung we should have as sudden an assurance of recovery as we had of its invasion. The discovery of the pneumococcus and its pneumotoxin as the indisputable cause of the disease, and the anti-pneumotoxin which produces the cure, are stepping stones upon the boundary of a great natural law.

Those of us who may be permitted to live another decade will see the benefits arising from this discovery, and will be able to arrest the progress of acute infectious diseases by injecting the products of the disease taken from convalescents.

The two grand divisions of pneumonia which differ none the less widely in etiology than in the mode of termination, will always be taught. The catarrhal form, which after all is only an ultimate bronchitis, the type of which is seen in infancy and as a complication in many of the exanthematæ, will not enter into this discussion. It will be understood, therefore, that whatever may be said concerning cardiac stimulation concerns the so-called croupous pneumonia only.

In all this time, regardless of the change of views as to etiology and pathology, men, women and children have been dying from pneumonia in no less numbers. In all this time, the mode of the approach of death has remained the same under any and all treatment, coming through the right heart—a distended right ventricle, a stasis in the pulmonary circulation and a corresponding emptiness of the arterial current.

It may be truly said that therapeutics follows the advance of medicine just as the coal cart follows the engine—always a reasonable distance behind. Just here I ask your indulgence for a moment while I quote some statistics from the most excellent paper of Dr. J. T. Jelks, of Hot Springs, Ark., who also quotes them from Dr. Townsend Coleridge and Dr. Wells' report of "Mortality of Pneumonic Fever."

*Read before the Medico-Chirurgical Society, Feb. 3, 1893.

These statistics are entitled to our consideration on account of the care with which they have been collected and from the acknowledged truthfulness of the author. From the first of these reports it appears that 1,000 cases of pneumonia were treated in the Massachusetts General Hospital between the years 1822 and 1890 inclusive. The average mortality was twenty-five per cent. From 1822 to 1832 the mortality was only ten per cent. In the latter report, the number of cases tabulated was 223,000, and these statistics include the various hospitals of America and Europe, and embrace the time between 1800 and 1890. The average mortality was $18\frac{1}{10}$ per cent.

Now in the first period of this time it cannot be doubted that the treatment was heroic in the fullest sense of that term as it applies to blood-letting, calomel and tartar emetic, for this treatment marked the first half of the nineteenth century. Now to make another division of the same report, the mortality in the last ten years has been twenty-eight per cent., and this must have included many cases treated upon the expectant plan advocated by Dr. James Hughes Bennett.

How then are we to harmonize the results obtained under a treatment long since condemned by common consent of the profession, with the results of the treatment of to-day under the broad light of modern pathology; in other words, the ten per cent. mortality in the decade between 1822 and 1832 with the twenty-eight per cent. mortality between 1880 and 1890. Were those Sangrado bleedings and those terribly depressing agents less active upon a stronger population, or did they, in spite of the evils which they could not fail to produce, strike at some underlying principle in therapeutics which we, with all our modern accomplishments, fail to recognize. I am disposed to the latter conclusion. Notwithstanding they come to us like a sound from the ringing rocks of past ages, there is to-day much truth in the statement that blood-letting is indicated in pneumonia. The period for its employment is at the time when the right heart is over-distended and is about to cease the performance of its function. More blood is coming into the right auricle than can be forced through the obstructed lung, and the ventricle is fagged out in the futile attempt to fill the left heart. The right ventricle is so distended at this time that the apex beat is completely removed from its original site in the inter-space between the fifth and sixth rib, and the ear detects a dull muffled sound, and percussion reveals an increased area of dullness. All this occurs at a time when the ptomaines from the vegetable pneumococcus are being absorbed into the circulation, and before the anti-pneumotoxin has been formed in the albumen of the blood. Experiments in vivisection have demonstrated that a heart brought to a stand still in such a diastole, may be revived by aspiration of the right ventricle.

The question may then be properly asked, where does the application of cardiac stimulation come in this condition? Is it philosophical to attempt the relief by a *vis-a-tergo*, or is it more rational to attempt the relief by a *vis-a-frontis?* Are these the indications for the employment of digitalis? It may be a good plan to goad the tired ox that has fallen in the furrow if you want a little more work. But you will have a little less ox. It may be good therapeutics to stimulate a diseased kidney with irritant diuretics if you want just a little more urine and a little less patient. And it may be good practice to give digitalis to a fagged out heart in the stage of hepatization in croupous pneumonia. But I doubt it. Digitalis stimulates a weak heart by contracting the arteries and arterioles, throwing the blood back upon the heart itself, and, where there is no pulmonary obstruction, the action is prompt and efficient. But the very condition which is killing the patient in pneumonia would be rendered still more dangerous by such an agent. It has been found that even ligation of the lower extremities just sufficient to prevent the return of venus blood, is followed by relief to the heart. The sense of relief felt by the patient upon the application of a hot flax-seed poultice, is in a large measure due to the dilatation of the blood vessels of the chest walls. Pediluvia also would prove of great service were it not for the ever present danger of assuming the erect position. Alcohol will prove a far better cardiac stimulant in pneumonia by reason of its power to dilate the capillaries, thereby retaining more blood in the skin, while at the same time it may have some value as a respiratory food. Nitro-

glycerine and the nitrites may be expected to rescue a heart after the manner of aspiration, and theoretically, would prove to be cardiac stimulants in the condition under consideration. I understand also that they have been of practical benefit. Cuppings, either with dry or wet cups, over the region of the inflamed lung have also been productive of relief. Very warm baths give almost immediate relief but are difficult of administration to adults. They are available in childhood.

It should be remembered that at one time veratrum viride and aconite superceded blood-letting. These agents, long considered identical in action, have nothing in common. The former does not weaken the muscular power of the heart and may have a place as a cardiac stimulant in pneumonia, while the latter is a highly dangerous drug capable, even in moderate doses, of paralysing the centers of Stechenow in the heart. Strophanthus is a far more effectual and safer remedy in the condition under consideration than is digitalis. Strophanthus acts upon the ganglionic motor centers in the heart, leaving the arterial tension alone. Caffeine is a cardiac stimulant by no means to be despised in pneumonia. The value of a cup of strong tea or coffee has been long recognized in domestic practice. Very small doses of strychnine may also be of advantage.

ASEPSIS IN OBSTETRICS.*

DR. M. R. MITCHELL, Topeka, Kan.†

Asepsis, as a comprehensive term, is applicable to three different fields in the struggle against the septic germ, viz: Prevention by cleanliness, by the removal or avoidance of such conditions as may cause putrescence or septicæmia; second, by correcting or counteracting septic infection already existing—antisepsis; third, by destruction of the septic germ—germicides.

The advantages of thorough aseptic management applied in the fullest sense in general surgery are to-day acknowledged by every one worthy of the name of surgeon. In fact the faith has become so strong and the practice so common, that the surgeon not using it is liable for mal-practice in case of bad results.

The principles of asepsis are as scientifically applicable to obstetric practice.

The prevention of puerperal sepsis is the all important phase of the subject, and it is this that I desire particularly to emphasize in this brief discussion.

The application of prophylactic precision can nowhere have a more useful place than the lying-in chamber. True it is that occasionally a case of puerperal sepsis cannot be cured, but very seldom is it true that it could not have been prevented.

As I turn my attention to this subject I rejoice and take courage at the thought that it has become of late days a topic of absorbing interest. It is being discussed by medical minds in cities, towns and rural districts with a great degree of practical intelligence and enthusiasm.

The croaker, crying out against all this as meddlesome midwifery, will soon be found only in the past.

Much responsibility is imposed upon the obstetrician of to-day. He is forced to contest the field with the abdominal surgeon for a record of the greater number of cases without a death. The country family physician is now set to thinking how he may compete with the city accoucheur applying his aseptic methods while on his rounds of work along the thickly populated alleys, byways and highways. Yes, and he finds, too, that he must improve his record in order to share honors with the maternity physician whose germ-laden hospital wards a few years ago were the slaughter pens of a large percentage of lying-in women.

The records of the New York Maternity on Blackwell's Island, or the Boston Lying-in Hospital, only a decade ago showed a death rate of from four to fifteen per cent.

But, after the introduction into these institutions of aseptic care, there was a speedy diminution of fatality. As these

*Read before the Western Obstetrical and Gynecological Association.

†Professor Obstetrics Kansas Medical College.

methods have been gradually developed and simplified to a high degree of accuracy and preciseness in all the minutiæ, to-day's record will show a series of five hundred labors or more without a death.

In the Transactions of the Obstetrical Society, of Philadelphia, of last January, it was reported that, at the Preston Retreat, there had been one thousand cases of labor without a death. And this report comes to us as the result of the skillful direction of none other than America's most successful abdominal surgeon and obstetrician, Dr. Joseph Price.

This institution is a model in all of the varied details of purity and cleanliness as well as of antisepsis.

Why this great gain in the saving of the life of parturient women?

What are some of the conditions attending the lying-in process which make it necessary to use such precautions in order to guard against puerperal sepsis? Although the phenomena of normal labor are physiological, yet there are pathological changes of a greater or less extent in every case of labor, normal or abnormal; and, as Dr. Price expresses it, "A woman during and after labor is a wounded woman."

In every child-birth there is, in addition to the utero-placental attachment, more or less contusion or laceration in some part of the birth canal. It may be the cervix, the vaginal wall, or the vaginal orifice. However insignificant such a lesion, it affords a possible entrance for septic infection—a disordered state which, in the words of Prof. E. P. Davis, of Philadelphia, "is identical with septic infection occurring in any recently wounded patient, whether it be a man crushed by machinery, whose wounds become infected during handling by the careless surgeon, or a woman whose torn perineum is infected during labor by the unclean fingers of her attendants." Again there is a greater or less depression of the nervous system, a lassitude and lowering of vitality which leaves the woman less able to resist septic influences.

As to precautionary measures in these cases I cannot enter into any detailed description, but will simply allude to a few leading points of procedure.

In a general way the patient should be surrounded with such environments that the dangers of infection may be reduced to a minimum, and the process of absorption and repair may be interfered with as little as possible, but encouraged in every way.

Proper attention is requisite before, during and after labor.

Before labor, there should be preparation of the patient by thorough bathing, and she should be furnished with clean clothing, clean bed, clean and well aired apartment. Labor begun, the rectum and bladder should be evacuated. The external genitals thoroughly washed with soap and water, and then bathed in an antiseptic solution such as 1 to 2,000 of bichloride of mercury.

The vagina should be douched with the same solution, or with a solution of creoline, hydronaphthol or carbolic acid. There should be but little manipulation of the vulva and vagina, and only with hands rendered thoroughly aseptic. All instruments and vessels used about the patient should be cleansed with carbolic acid and boiling water.

Following normal labor, the vaginal canal should be douched once with a solution as before labor. The external genitals should be cleaned and bathed with the bichloride solution, antiseptic gauze with a pad of folded napkin, or better, of absorbent cotton, applied. The vulva should be thus cleaned and dressed every four to eight hours until the cessation of the lochial discharge.

Throughout the puerperal period any evidences of septic infection from decomposition of lochia, blood-clots, or membranes should be promptly met by antiseptic vaginal douches, and even intra-uterine, if that organ is involved. If the bichloride solution is used, it should be of the strength of 1—5000, followed by douche of boiled water.

Dr. E. E. Montgomery suggests iodoform gauze rope introduced intra-uterine for drainage in these cases.

Another essential procedure is to shut the doors of entrance for sepsis, viz.: the veins, lymphatics and fallopian tubes, by promoting uterine contractions and aiding other physiological processes of restoration.

The course of puerperal sepsis can be readily apprehended when we recall the anatomy of the lymphatics in the vicinity of the genital tract. And remembering the ready access of infecting germs through

these channels in freshly made wounds, we can realize the speedy involvement of the numerous glandular structures in the vicinity of the pelvis, extending possibly to the uterus, its appendages, and the peritoneum. Hence we will have such inflammatory conditions as vulvitis, vaginitis, metritis, ovaritis, salpingitis, and peritonitis.

A very important consideration in connection with this subject is the fact that the fatality from septic infection is only *one* of its far-reaching results. A very large number of mild cases of sepsis, and which are mostly lost sight of by the general practitioner, become in after years, the victims of wrecked health, a life of suffering and of an untimely grave.

The work of the gynecologist to-day is largely traceable to the dirty finger nails, or the personal indifference to the simple, practical and important details of asepsis on the part of the obstetrician.

When Dr. So-and-so relates his large experience in confinements without an instance of septicæmia, and that too without the observance of the new-fangled aseptic precautions, the only rational conclusion is that the true cause of the chronic ill-health of many of his patients has not been peceived by him, and his boasted experience is practically equivalent to the confession that he is unable to recognize the presence of mild sepsis.

Since the attention of the profession has been directed to aseptic practice, the progressive tendency in technique has been to greater simplification in the details. And that is to-day the best method which affords the safest protection to the patient, and which is most easily and readily applied in the every day practice of the physician.

SOCIETY REPORTS.

THE LOUISVILLE MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, February 3rd, 1893.

The President, Dr. F. C. Simpson, in the chair.

CASE OF EXTRA-UTERINE PREGNANCY—OPERATION; RECOVERY.

Dr. A. M. Cartledge: I will just briefly run over the history of a case before showing the specimen. Some three weeks ago I saw a lady, 36 or 37 years of age, who was suffering with severe pain coming on suddenly in the right side of the chest, which proved to be an ordinary pleuritic attack very well marked at first, and subsequently followed by a slight effusion. After a week or so she recovered from the attack of pleurisy, was about the house, and and getting along fairly well, so much so that I had not seen her for four days. I was again called to see her fourteen days ago. She was complaining of excessive pain in the right side, referred particularly to the region of the appendix. This pain was described as being very intense, having existed all night. I saw her in the morning. She displayed a well-defined tenderness right over the McBurney spot, midway between the umbilicus and the anterior spine of the ilium. I believed that I had a case of appendicitis, but temporized for the time being. Her temperature at that time was 101°F., pulse about 100. I saw her again in the afternoon when she expressed herself as being much easier. This state of affairs continued for two or three days. About the fourth day I detected a slight lump in the right side over the region of the appendix, about the size of a duck's egg, which was very tender, but there were no evidences of general peritonitis. Pulse now about 120, temperature 102° F. I advised operation, supposing that it was a case of appendicitis. This was refused.

The case went on from day to day, the enlargement in the right side increasing all the time. I thought I could detect a well-marked fluctuation in this tumor. It was very tense and was typically in the appendicular region, reaching up above the McBurney point, and, taking everything into consideration, it seemed about as clear a case of appendicitis as I have ever

seen. Last Tuesday the patient complained of pain about the median line just above the bladder; tumor in the right side practically unchanged. I was becoming very uneasy about the case and urging operation. Wednesday morning pulse about 112, temperature 100° F. She complained about a week ago of some little shivering sensations. I told her that she must either consent to an operation or consult another physician, as she was certainly growing no better. She consented to the operation, which was performed last Wednesday. Believing that I had an abscess around the appendix, I made the usual incision over that organ, dissecting down carefully until I reached the sac. Then with a small incision about an inch in length covering the sac proper, I found there was no peritoneal adhesions in front because I could see some fresh peritoneum; in fact the abdomen was already open. It was my first intention to expose the sac, wash out the cavity thoroughly and remove the appendix which was supposed to be diseased. I then broke the very superficial adhesions in front, passed my hand around and located this tumor, about the size of an orange. I found the adhesions quite extensive, especially to the colon. I now commenced separating the adhesions leading down to what I supposed was the appendix, and in lifting up the intestines was very much surprised to find the tumor easily freed from from its superior attachments. I packed gauze around the intestines to get them out of the way thoroughly. I then drew the tumor up into the wound and found it necessary to enlarge the incision in a backward direction. In removing the tumor the sac was ruptured and was found to contain probably a pint of fluid. When this fluid ran out of the sac as the woman was lying on her side, something dropped which led me to stoop and pick it up and lay it aside. The sac was now discovered to be the right tube and ovary which were tied off and removed. The cavity was thoroughly cleansed and the patient put to bed in a very fair condition.

An examination of this specimen proves it to be unique indeed, as one of extra-uterine pregnancy occurring about as near the ovary as we will ever see; a condition that is denied as you are all very well aware, by some very eminent authorities, among them Tait, claiming that all cases of extra-uterine pregnancy are tubular in character. I believe this is a typical case of impregnation of the ovum just as it was being released by the ovary, the artificial uterus being the ovary itself. The tube is entirely intact. I will state that there is no history of recent cessation of menstruation, and none of the usual symptoms of extra-uterine pregnancy. How old it is I do not know.

What I want to call especial attention to is to the fact that the artificial uterus is the widely separated ovary or ovarian tissue. This patient has had one child, about fourteen years ago. She has since made an uneventful recovery.

DISCUSSION.

Dr. W. O. Roberts: I think a microscopical examination ought to be made of the specimen to determine to a certainty whether or not it is a case of extra-uterine pregnancy.

Dr. J. G. Cecil: I would not be able to give a positive opinion in regard to this case from the history given; certainly the ovary is present in the specimen and the fimbriated extremity presents a cavity which may be the cavity of an abscess, a hemato-salpinx, or it may be an extra-uterine pregnancy. I think it could be very easily demonstrated by a microscopical examination. If it be extra-uterine pregnancy it should show evidences of fœtal structure. However I do not think it is by any means conclusively demonstrated thus far.

Dr. A. M. Cartledge: It did not occur to me that there would be any difficulty in recognizing the nature of this pathological specimen microscopically, or I would have had it microscopically examined before presenting it; this, however, will be done later.

I have detailed the history very carefully, and I would like to ask the surgeons who may be inclined to the belief that it is a case of pyosalpinx, if they ever saw pyosalpinx so large as this without pelvic peritoneal adhesions. I do not see what could possibly be suggested except extra-uterine pregnancy. Even if microscopical examination reveals no evidences of a fœtus I shall still think it extra-uterine pregnancy, and that the fœtus has entirely passed away—has become digested.

Dr. A. M. Vance: Do I understand, Dr. Cartledge, that there was never a case of pyosalpinx without adhesions?

Dr. A. M. Cartledge: I have never seen a pyosalpinx one-half this size without peritoneal adhesions and do not believe it ever occurs.

Note: A subsequent microscopical examination by Dr. Vissman of the body found in the sac, reveals clearly fœtal and placental structures.

Dr. John A. Larrabee presented an essay on the subject

CARDIAC STIMULATION IN PNEUMONIA.

(See page 364)

DISCUSSION.

Dr. Wm. Bailey: I am inclined to believe that there is something in what Dr. Larrabee has brought before us in his paper. However, it is not entirely new. I remember the same question came up in the section on medicine in Detroit last year. It was advised instead of digitalis that we use nitro-glycerine for dilating the capillaries. Others claimed that nitro-glycerine gave no better satisfaction than digitalis. However I do believe that in very many of these cases digitalis is advisable when the conditions indicate that the heart is over-worked and it becomes necessary to contract the arterioles. Of course I can conceive how digitalis in other cases would not give relief. I should hesitate a long time before discarding a remedy so valuable as digitalis and resorting to other stimulants which do not contract the arterioles to the same extent.

Dr. A. M. Cartledge: What would you consider an indication in pneumonia for the administration of digitalis or any other stimulant? How long would you wait?

Dr. Wm. Bailey: I believe the principal thing in the treatment of croupous pneumonia is the management of the heart. I would put the patient in the best possible condition and assist the heart by medicine if necessary, and when it became evident that the right heart was being over-distended, then I think the introduction of a cardiac stimulant imperatively demanded. I am not quite ready to admit that I can always tell when the right heart is over-distended by auscultation, percussion, change of pulse, etc., because these phenomena may not be very manifest. Certainly I think in these cases the higher the fever the greater the danger to the heart, just as it is in every disease in which high temperature is a factor.

Dr. D. T. Smith: The conclusions as stated by Dr. Larrabee in regard to the use of digitalis are those which I have reached some time since, and I heartily indorse all he has said. My experience with this drug in pneumonia has been such that I feel justified in saying that it should be used with extreme caution.

Concerning the microbic origin of pneumonia: Notwithstanding the recent so-called discoveries and theories in this direction, I am still in extreme doubt. This is not directly in line with the subject under discussion, but I will state, in regard to the epidemic nature of pneumonia, when we see that a little change in the atmosphere from British Columbia to the Gulf coast will spread pneumonia throughout this whole territory within a time limit of two or three days, it would seem that there is something beyond the microbe to cause it.

As to the treatment of cardiac failure in pneumonia: Of course the condition of the patient, as to age, strength, etc., and the extent of the involvment indicates the danger. The portion of lung involved we have nothing to do with, other than to endeavor to secure its protection until the forces of the system can bring about resolution. I can hardly see the necessity for commencing cardiac stimulation at the beginning of an attack, as is claimed by some authorities. This treatment should be instituted only when there is evidence of failure of the heart to properly perform its functions; I do not mean the fatal failure, but when the heart fails to send the blood through the affected lung in the proper quantities to effect adequate oxygenation.

I have been in the habit of using digitalis but always in small doses. I think our aim should be in these cases to improve the general system of the patient, and as far as possible give medicines that will not disturb the digestion or appetite. A year ago I was called in consultation to see a case of grip and pneumonia in a very aged patient; I hardly thought it was a case where digitalis should be given, yet as my consultants advised its administration, I felt no harm would be done. One-twelfth of a grain of digitalin was given in twenty-four hours—one-sixtieth of a grain every four hours. Very unfavorable

symptoms developed lasting for several days. I have no doubt that owing to the condition of the patient at the time, this was too large a dose.

I believe alcohol is very valuable as a cardiac stimulant in these cases. I would also advise the use of strophanthine, which acts without contracting the arterioles. In the use of a drug which contracts the arterioles it seems to me that the heart is given a greater amount of work to perform, hence I fail to see the advantage of such treatment. Strychnine is also of service in these cases, as it acts as a steady stimulant on the heart's action and acts upon the stomach in increasing the power of digestion and desire for food. I want to emphasize the fact that I believe digitalis should be used with extreme caution.

Dr. J. A. Larrabee: In closing I would like to avail myself of the opportunity of thanking the fellows of the society for their consideration of the subject presented, and am sorry I did not hear part of the discussion. My attention was brought to this subject very pointedly in this way: I have seen numbers of fatal cases of pneumonia in which digitalis was being administered, and was impressed with the fact that we were not getting the effect that digitalis ought to produce. Instead of increasing the force of the heart's action and having generally a good effect, the opposite was the result. Then in looking up the statistics, as stated in the paper, there is something in this point. Blood-letting, although producing so many evil results, as we grant it does, evidently strikes the all important point in the treatment of pneumonia, as is shown by the statistics between 1822 and 1832—the mortality being but ten per cent. I became convinced, as Dr. Smith has said at the bedside, that digitalis did not and will not produce the good effects claimed for it. It is like introducing ergot into a full bladder to expel the urine instead of using a catheter to draw it out.

The point made by Dr. Bailey is one of considerable importance, especially in croupous pneumonia. The greater the pulse and the higher the temperature, the greater is the danger from digitalis.

THE WESTERN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Annual Meeting: Kansas City, Missouri, December 27th, 1892.

[OFFICIAL REPORT.]

MORNING SESSION.

Transaction of business was followed by the annual address and the presentation of papers.

Dr. M. B. Ward, Topeka, Kan., delivered the

PRESIDENT'S ADDRESS.

Fellows of the Western Association of Obstetricians and Gynecologists:

We are convened to formally inaugurate the Western Association of Obstetricians and Gynecologists and to enjoy the mental feast, rare in quality and sumptuous in quantity, which we are assured is in store for us.

As an association, we are yet in the stage of lactation. One year ago a meeting was held in Topeka for the purpose of organizing this association, which was attended by only a few of the number who had expressed their desire to aid in forming and maintaining such a society. Those present were enthusiastic regarding the propriety and necessity of such a society in the West.

An organization was consummated, bringing into existence the Western Association of Obstetricians and Gynecologists.

The parturition was normal; no instruments were employed; no rupture occurred to mar the perfect symmetry of the accouchement.

No programme having been prepared, nothing remained to be done with the fledgling but to wrap it in the mantle of time, and place it in the arms of our genial secretary, Dr. T. J. Beattie, who has so tenderly and wisely cared for it during the first year of its existence, that

we are enabled to celebrate with delight its first birthday, on this occasion.

I most heartily appreciate the honor of being the first president of an association whose inauguration is so auspicious and whose permanency is assured.

It is usually expected that the presiding officer will deliver, sometime during the session, an inaugural address, and it was my purpose to have carried out the established custom. But owing to a recent long and serious illness, from which I am not yet fully recovered, it has been impossible to suitably prepare such an address. I, therefore, beg your kind indulgence while I make a brief retrospect of the original plan of the organization, and a prospective view of the possibilities of the association.

Perhaps it was in accordance with the eternal fitness of things that a Kansan was prompted to take the initiative in organizing this society.

In making this reference which is intended to give Kansas credit for inaugurating many important movements that have given her a record of which all lovers of liberty are justly proud, I do not wish it to be understood that I am unmindful of the deplorable fact that, of recent, she has led in schemes whose very foundations have been carious, and the results unworthy the fair name of Kansas.

The western states are attracting universal attention on account of their wonderful resources and the prominent part they are taking concerning all great and important questions.

In no other direction are we so weak and insignificant as in the position occupied by the medical and surgical profession, as compared with the eastern states.

The East may be justly termed our Fatherland so far as concerns our profession, and we are obliged to confess that that section is entirely worthy of the honorable title.

It is to the distant East that each and all must journey if we are to gather the ripest, juiciest and richest fruit pertaining to our professional progress.

How favored, indeed, are those who are so situated that they may frequently wend their way towards this Mecca of medical and surgical knowledge.

After several visits to the East, it occurred to me that the West should at once organize a society whose aim would be to educate those whose relations and circumstances prevent frequent visits to the more favored portion of the Union, and at the same time aid in diffusing the leaven throughout the whole loaf, which comprises thousands of struggling physicians who cannot enjoy the advantages of the far-distant metropolis.

In the early fall of 1891 a circular letter was sent to about fifty prominent physicians, who were practicing obstetrics and gynecology to the more or less exclusion of the other fields of medicine and surgery, and who reside in the states of Missouri, Iowa, Nebraska, Colorado, Kansas, and the territory of New Mexico, soliciting their opinions regarding the advisability of forming a society in the West, whose special aim should be to advance the science of obstetrics and gynecology, and whose active members should be those only whose practice is limited to these special branches, or who desired to give special attention to these branches of the practice.

Favorable reply was received from nearly every physician addressed, and a meeting to complete the organization was held in Topeka, the last days of December, one year ago. .

The growth and usefulness of this organization are now assured, if the present status is a correct index of the future.

Our society should be a practical educator, sowing the seed of modern pathology and therapy in good soil, which will increase one hundred fold; in shallow soil that may not yield more than fifty fold, and, if necessary, on stony soil which may not for the present show any signs of increase, but some of the good seed may find nutrition sufficient to make a sapling whose influence will tell for truth sooner or later.

Oftentimes is it true that the dullest lad makes the most brilliant man.

Let us not despise the day of small things, though we are few in number and yet unrecognized by the medical and surgical world.

I am not certain that the plan which has been formulated for the government of our society is sufficiently broad-gauged.

In this connection I heartily recommend that a committee be appointed who shall consider this feature of the organization and suggest any change in our laws

that they may conclude will tend to increase the scope and usefulness of the society.

We should endeavor to make the programme exclusively of topics pertaining to obstetrics and gynecology,—but the surgical aspect of these branches should have such recognition as will draw to our meetings the general as well as the special surgeon.

While we would not expect ophthalmologists, and laryngologists to prepare papers on their special branches to be read before our society, yet they, and all other specialists should be encouraged to note carefully the relations of diseases, so that should their patients suffer from trouble entirely reflex, they may add their rich and varied experience, which would educate others who would not have such opportunities of observing the sympathetic relations of disease.

The general practitioner should be enticed to our meetings through the channel of the inseparable relations which must forever exist between them and the specialist.

If general practitioners could have the opportunity afforded the specialist in diagnosing obscure pathological conditions, their usefulness would be greatly increased and untold suffering avoided.

In conclusion I would urge the society to strive to secure the co-operation of prominent members of the profession who reside in the eastern and southern states, that we may have the benefit of their cultured experience and wise counsel.

On behalf of this society I extend to our friend, Dr. Joseph Price of Philadelphia, one of America's greatest obstetricians and gynecologists, who is present with us, the freedom of the floor, and cordially invite him to fill our granaries out of his rich and overflowing storehouse of knowledge.

We are to be congratulated that so distinguished a gentleman has honored us with his presence.

AFTERNOON SESSION.

THE VICE-PRESIDENT, Dr. Shreves, in the chair.

THE CHAIRMAN: According to resolution the first part of this afternoon is to be taken up in criticism upon the papers read. The first then will be upon the paper of Dr. M. R. Mitchell, of Topeka, Kansas, "Asepsis in Obstetrics."

It was then moved and seconded that the gentlemen present, not members of the society, be given the privilege of the floor in discussion. Carried.

THE CHAIRMAN: Dr. L. A. Berger was appointed in case Dr. Woodson was not present, to open the discussion of this paper.

DR. BERGER: In view of the fact that our time will be somewhat limited I will not take up very much of it in discussing this question, but will make a somewhat short resume of the paper read by Dr. Mitchell. The society is to be congratulated that the subject of *Asepsis in Midwifery* has been selected as the first paper. Asepsis is the ground-work of all our work both in obstetrics and in gynecology. The most important truth that is impressed upon us by our experience with antiseptic measures in general and in surgical practice is this, that *cleanliness* is the foundation of all successful surgical and other work. A proposition has been made that every woman who has undergone accouchement is a wounded woman. I would add to that that every pregnant woman is an anæmic woman, and is entitled to the same care and the same attention that is given to any surgical or medical case. The great fault with us in our general work is that as physicians we do not instruct our patients of the necessity of asepsis—of absolute cleaniness. In this lies almost the greatest trouble in carrying out strict antiseptic and strict aseptic measures.

From statistics, not alone in this country but in the London General Hospital, we find that the mortality has been reduced; in the latter from 40 per cent. to 2.5 per cent., and in this country from 20 per cent. to 1.5 per cent. This should be and is evidence to us that asepsis is an absolute necessity. It seems strange that we have not made more progress than we have.

The question whether puerperal septicæmia is due to auto-infection or to hetero-infection is, as you are aware, a mooted one. But granting it is due to one or the other is no argument against asepsis. This infection we know of a surety may be carried by the physician himself. Why is it that to-day without any tremor, with-

out any trepidation, without any fear we go from a case of scarlet fever or diphtheria, or even from a case of puerperal septicæmia to an ordinary case of confinement? Simply because we have a safeguard in asepsis.

We are all agreed, I believe, that asepsis is simply a question of degree. It is simply a question of how one man may carry it out or how another may; but underlying it all is unquestionably cleanliness. The prophylactic measures that we may use I would illustrate by my own personal experience. The conclusions that we reach upon all these questions are based simply upon each and every man's individual experience. At the University Medical College for the past five years, in my obstetrical clinic, which began with some six patients, and in the past year provided for some eighty cases attended exclusively by medical students, we have not had one death. Our methods are based simply upon the same principle that Dr. Mitchell brings forward so plainly. We intend to render those who attend these cases positively aseptic. They may start immediately from the dissecting room to these cases. We provide them with all the means and measures for antiseptic dressings and attention. They are supplied with permanganate of potash, oxalic acid, carbolic acid and bichloride of mercury. Understand, gentlemen, that these cases are taken from every part of the city, including the north end near the river—from the slums if you please to call it so.

When the students arrive they first wash their hands and arms to the elbow in a bichloride solution, then in a saturated solution of permanganate of potash and finally in a solution of oxalic acid. The patient herself is provided, if possible, with fresh, clean underclothing. Very rarely is this the case when they arrive. The patient's limbs and abdomen are washed with the carbolic acid solution and the labia washed and dressed with a bichloride solution. An injection is made also. You understand, of course, that all this is done if there is sufficient time before labor takes place. The injection is of a bichloride solution of 1 to 3000. These directions are faithfully carried out. The gentlemen are not allowed to make any examinations with lard or vaseline or any preparation that the family may have in the house, their hands are dipped in a bichloride or carbolic acid solution. I make no limitations as to the number of examinations. They can examine as often as they wish, but between and before each examination they are compelled to wash their hands either in the bichloride or the carbolic acid solution—preferably the bichloride solution. Furthermore, they are provided with a pad to catch all discharges, both before and after the confinement. After the confinement has taken place the patient is washed and cleansed thoroughly. No injection is made of any of the disinfectant preparations. Ordinarily we use the obstetric binder. The obstetric binder, I will state, is simply a matter of convenience—a matter of preference—and we use it simply to meet a whim, as it were, of the women. The vagina is inspected to see if there are any lacerations. If so, and the laceration be superficial, the attendants are instructed to touch it with carbolic acid. If the perineum is torn or if there is any special laceration they send for me and I attend to that myself. After the patient, thoroughly cleansed, is placed in bed, we use a pad made of bichloride gauze and absorbent cotton. Sufficient gauze and cotton are left, with instructions to the patient to change it every six hours.

This in brief is the method we have been carrying out for the last six years. And personal experience, that which one meets with in daily life, is the best evidence of success.

Dr. Sheldon: The only question I wish to discuss is whether the recommendation of the author as to the use of the douche after every labor, is altogether good. It seems to me, Mr. President, that it is not essential, nor proper, nor advantageous in every case to use a vaginal douche after delivery. If the necessary precautions as outlined by Dr. Mitchell, have been taken there is certainly no indication for the use of the douche. On the contrary, I can readily understand how the vaginal douche can, and often does, convey germs into the vagina and to the lacerated tissues wherever they may be, where they find a proper field in which to develop and grow.

Nature has well provided for cleansing the vaginal canal in the various steps of parturition. Almost continually for

some hours, or even days perhaps, before labor there has been a discharge which has constantly washed the vagina with an aseptic fluid. Then comes immediately or soon before the birth of the child, a flow of an aseptic fluid which further cleanses the canal. Following these, as if they were not enough, we have another process, and that is the passage of the head of the child through the canal, which certainly must further relieve it of infectious matter, if there be any. But that is not all. It seems as if Nature has provided a large cloth or mop, in the shape of the placenta which wipes it again and which with the flow must pretty thoroughly cleanse the canal. Now, as if that had not been enough, Nature provides another step, and that is the lochial discharge that continues for one, two, three or four weeks, as the case may be. It is hardly possible for any germs to enter the vaginal canal and lodge on those ruptured places in the mucous membrane, with all this antagonism to their entrance. We ought to remember, Mr. President, that as soon as the child is born and the placenta is delivered, the vaginal walls close down upon one another and there is no canal for the introduction of germs. It is closed; and this fact, in connection with the lochial discharge, which itself is an aseptic fluid, is eminently sufficient to prevent the introduction of any germs.

Just one more point. Suppose, as is usually the case, there has been more or less laceration of the mucous membrane in the vagina, or about the cervix, or slightly perhaps of the perineum. We do not say that it is extensively lacerated because that comes under another head. But suppose we have a ruptured mucous membrane in the passage. I would like some one to tell me what we are to accomplish by the vaginal douche after the labor. Isn't it a fact that if you use the vaginal douche with an antiseptic of greater or less strength, immediately or in a very few minutes thereafter, the whole surface is again flooded with a lochial discharge? Again, if you use antiseptics or germicides strong enough to destroy any germs that may exist in the vaginal canal, you will use antiseptics or germicides to injure the tissues more than do them good.

Dr. Todd: Mr. President, I want to speak upon a particular point, inasmuch as it appears to me that the speakers as well as the author, have omitted something very important. I wish to call your attention to the fact that, while asepsis or cleanliness is all that is claimed for it by the speakers, something more is needed. Asepsis excludes infection from the outside; but all infection is not hetero-infection. Now I wish to say that, during the labor or about the termination of the labor, besides resorting to these antiseptic measures we should see that the uterus is firmly contracted and that all coagula are thoroughly expelled. We should see that there is a firm contraction of the organ; for in that way these torn vessels are closed so that if a small coagulum remains there will not be decomposition, and the danger of absorption is at a minimum. The idea is to so close these bleeding vessels by contraction that there be no more bleeding, and that even the smallest coagulum shall be expelled. Thus there will be nothing to undergo decomposition and be absorbed by the lymphatics and veins, and asepsis will be preserved. Understand, I do not undervalue the importance of asepsis, but that is not all; and, speaking from an experience covering thirty-five or forty years and extending back to a period long before asepsis was known, I could give a record that would astonish you. Cleanliness was the means by which infection was prevented and the recovery of the patient assured. It would astonish you to know how much could be done without any knowledge of asepsis. But I do not depreciate the value of asepsis at all, for now-a-days, with the aid of all these aseptic precautions, very few patients need die in a puerperal condition.

Dr. Dewees: I wish to endorse in a measure what has been said by the speakers thus far. One point I wish to insist upon and to place myself on record, is that our office as obstetricians, is simply as overseers and helpers. First, as overseers we are simply to watch and see that Nature is doing all that need be done. So long as Nature fulfills her part, so long are we, above all things, not to become meddlesome. As helpers, we are simply to act when we find that Nature is obstructed in one way or another. These offices are fulfilled, as Dr. Mitchell suggested, as to the external part of the woman; but as to the internal douching, I wish most strenuously to disapprove of the procedure un-

less there is a septic condition calling for its use. Once the woman is clean and the physicians' hands are clean, there is no more harm in introducing a hand or finger into the vagina or womb than there is in introducing it into the mouth. As for cleanliness of the hands of the obstetricians, I know of nothing better than the use of cyanide of potassium, the most powerful microbicide that we know. True, it may be dangerous if one has excoriations on the hand, but otherwise it is not dangerous and is an absolute cleanser. Subsequent to that, I use nothing but salt and water. I invariably have a pitcher of hot water brought into the room by the nurse, and into it I put enough salt regardless of quantity, to make a good strong salt brine. I have that covered, and pour a little into a basin as I need it. At the beginning of each examination I dip my hands into it and make my examinations, after which I use clean water and soap.

Dr. Todd: I wish to supplement my remarks by saying how the uterus should be compelled to contract and to expel anything that should come away or that might by remaining decompose and be absorbed. Just at the close of labor I resort, as I presume most physicians do, to the Credé method. But I want to call particular attention to the value of it to compel contraction. I don't leave off compression until the uterus is firmly contracted to a hard ball beneath the hand; and when that is done, I know that there is no coagula lodged in its cavity and no coagula lodged in the vagina. To make sure of this, I am in the habit of allowing my patients to get out of bed to defecate or to pass urine, no matter if it is only an hour after delivery. I allow them to get out of bed or walk across the room; I mean I don't restrict my patient to the bed. Those who do will find trouble from coagula remaining in the vagina. Besides, if put upon the feet the motion will assist the uterus to contract and expel the coagula. By a kneeding with the hands and the motion of the patient you can compel the uterus to completely evacuate its contents.

Dr. Dannaker: Speaking of asepsis in obstetrical practice brings to mind a case of long-delayed delivery, where the amnotic fluid came away at four o'clock in the afternoon. I was called near six o'clock the following morning, and on examination, after going through all the preliminaries, cleansing my hands and the parts—I always carry a fountain syringe with me for the purpose of cleansing the vagina—at first on making an examination I could'nt make out the os, but by putting my finger back I came into contact with the sacrum. Then putting my finger in the os and bringing it forward I could make out the position of the fetus. I applied the forceps, but during all this time I kept the parts thoroughly douched with hot water—no antiseptic whatever,—and brought the child into the world by this process. By this application of hot water to the vagina I had no trouble in the after-recovery of the patient. That is one particular point I want to make when you have those long-delayed deliveries where the amniotic fluid has come away, it is necessary to keep the parts softened, and the only way to do it is by this hot water application.

I wouldn't feel safe in using a carbolized solution any length of time, or a bichloride solution; but by the use of hot water you have all the effect necessary and in addition, you cleanse out the vagina, bring on the contractions and help the woman towards recovery. In regard to vaginal douches after the child has been delivered, and the after-birth discharged, I not only use my finger on the pulse, but use my nose. Every time I come, I lift the bedclothes and use my nose, and if there is the slightest odor I do not hesitate to order the douche, and I administer that douche myself for the purpose of cleaning out the parts. I think it is absolutely essential in all cases where there is the slightest odor. It behooves a medical man to use his nose just as much as a thermometer in those cases.

Dr. Shreves: There is one point I had hoped some member would notice, and that is the use of the vaginal douche prior to the birth of the child. If we take this as good practice, we must acknowledge that Nature made a sad mistake from the beginning. From twenty-four to forty-eight hours prior to the delivery, we find the vaginal tract thoroughly lubricated with a tenacious mucous secreted by the mucous follicles surrounding the tube, evidently the original design of Nature. Now if you use the vaginal wash prior to delivery of the child, you

wash away this lubricating fluid and leave this membrane denuded of that material placed there for its protection. With regard to the after-washings I would take the view of the other gentlemen, and say that it is only necessary when there are indications of septic influence. Especially is this the case where you haven't an experienced nurse. If you have an inexperienced nurse the probabilities are that she is a little bit timid and the water may not be quite warm enough and she may do harm; while if you have an experienced nurse, no harm will come from washing the vagina every day. But unless there are indications of septic influence, and unless there should be a foul odor present, I wouldn't direct my nurse to use the douche every day. But in case there was an odor, whether the nurse is experienced or inexperienced, I would direct the use of the douche if it was not possible to administer it myself.

Dr. Mitchell: I thank the gentlemen for the discussion of the two or three points to which attention has been called, and to which issue has been taken. The first one is in regard to the use of the vaginal douche, either previous to labor or subsequent to labor. It has been objected to because it is not necessary; because it removes an essential fluid used for lubricating the parts, and because it is risky or dangerous. It has been argued that it is not to be used unless it is needed, and that is when you have a septic condition. A septic condition, of course, would necessitate or make proper its use. Now, as I tried to make it appear in the paper, aseptic manœuvers are largely for prevention. If we are liable to have a septic condition, which all the gentlemen have virtually acknowledged, I think that liability is sufficient evidence to prove that precautionary measures should be used.

I cannot see why the douche is, or can be, injurious in any way, especially by removing or washing away the secretions that serve the purpose of lubrication. We know that those glands secrete freely and continue to secrete, and the supply is not wanting when the passage of the child comes. Even if you do use the douche previous to labor, the reproduction of this secretion is not affected and lubrication is plentifully supplied.

As regards the danger of introducing septic matter by use of the douche, if you conduct your procedure with strict care in every particular there is no necessity for introducing any septic material whatever.

I admit that the vaginal discharges are usually aseptic, but very frequently they are not. Why is it that we so frequently have endometritis? It is on account of secretions in the vagina, and I think the majority of women previous to labor have more or less leucorrhœal discharge which is not aseptic and which is liable to become septic on a lacerated surface. I referred to the method of contracting the womb in my paper, but perhaps I did not put enough stress upon that point and I am glad the doctor has presented it. It is certainly one of the necessary and, indeed, the most important of procedures to obtain and preserve aseptic conditions; that is, shutting the doors and preventing the entrance of septic material. Thorough contraction of the womb, and seeing to it that it continues contracting, is a very essential part in connection with aseptic treatment.

I think the use of hot water very good. Hot water is a very good material to use in promoting or in preserving an aseptic condition. In fact, I very frequently use it as a vaginal douche—simply boiled water as hot as the comfort of the patient will admit of.

The Chairman: As Dr. Price has just arrived I will say for his benefit that there has been quite a little discussion upon this paper, and that the privilege of discussion is extended to all present and is unlimited as to time. We shall be very glad to hear from you.

Dr. Joseph Price: I value the discussion of papers sometimes very much more than the papers themselves, and I am very glad to hear the Chairman say that there is no time-limit to the discussions. Unfortunately in our society meetings in the East we have limited the time to three or five minutes. We have been governed very much by the Marquis of Qeensbury rules—three minutes to a round. That men of average experience, who have traveled a thousand miles with the best they have and the best they know, should be rapped down in three minutes is a mistake. But it is so in all our national organizations and in our state societies, and there should really be some stop put to it. It keeps a number of good men away from county,

state and national organizations who have something to say that is valuable and which should be placed on record.

Dr. Mitchell very kindly referred to the Preston Retreat in Philadelphia. It is an institution more than fifty years old. It hasn't that polish and shine about it that the Sloan Maternity of New York, or the Hopkins of Baltimore, have, but the construction and arrangement of the institution is about perfect. In short I feel that most new institutions would do well by patterning after this old one.

It is of very peculiar construction; a large square building with a veranda surrounding at least two-thirds of it. The wards are entered from this veranda; the wards touch the house on one side only and are isolated. It is peculiar in its cruciform shape, favoring ventilation. The plumbing is all outside of the building not inside; at least, it has been so since I have had charge. There is not a pipe in the building. You can all very well remember that the privy was back of the garden when you were boys. Later, it was moved up to the house side of the garden; still later into the back yard; the next move was up *against* the rear of the house, and the next move in the rear of the house just *inside*, and now our houses are simply hoppers to a sewer with the plumbing all amidship. What we call modern sanitary plumbing is tapping the sewer at the first, second and third floors in our homes and residences. There is no reason why all plumbing should not be outside the house by three or four feet, with a circulating atmosphere between the house and the pipes. This should be so in all houses and hospitals. No hospital should have plumbing *in* it of any character whatsoever. *Always* there should be a *circulating atmosphere between* the plumbing and the house or hospital.

Now as to the isolate work of the Retreat. The wards are large, well lighted and well ventilated. In the paper referred to, all of this was dwelt upon at some length. The ceilings are high; the wards are wide, the windows are large and there is an open fire as well as modern methods of heating. The plumbing is distanced. There is a circulating atmosphere at two points between the wards and plumbing proper in the brick piers at the corner of the house continuing from it.

The toilet of the patient is just about that given in the paper. The patients are admitted theoretically two weeks before delivery—a wise provision for a woman approaching the perils of childbirth. This unfortunately has not been so in the maternities all over the world. I think it is simply cruel to admit a woman in labor, and to discharge her on the tenth day—simply cruel. It isn't right, and should be stopped. At the Retreat they are admitted two weeks before, and they may remain four weeks after. You see the period is much longer than in any other maternity. When admitted to the house the patient has a bath—a thorough bath; her soiled clothes leave the building and go to a laundry some distance from the hospital. While awaiting delivery she takes two soap baths a week; the bowels are kept soluble, and if there is a suspicion of any renal trouble, the urine is examined. When she complains of labor pains she is given a soap bath, a vaginal douche of 1 to 2,000 bi-chloride of mercury and an enema, and she enters the delivery room in clean clothing.

The delivery room is cared for by a clean nurse who has nothing whatever to do with the puerperal patients while caring for the delivery room. The nurse and doctor both scrub thoroughly before entering the delivery room. I allow but few examinations and but little meddlesome midwifery. I examine the patient only once and go off and read, or lie down until the head is about ready to clear the perineum. The forceps are very rarely used. The woman and nature still know how to do their own work. The women are permitted to have their own children and I find it a wise if old fashioned practice.

At the present time there is unquestionably, in private and in public, a tendency to make too many artificial deliveries. And just here, had I the time to demonstrate the mischief and evils of the premature application of the forceps or of hasty delivery, I think I could add something at least, to the list of vicious sequellæ of child-bed that we are so often called upon at present to repair. In short I am satisfied that foolish obstetrics is responsible for so many private sanitaria, and for so many gynecologists established over the land. Lacerations are bound to occur. No doubt there were lacerations in Eve's cervix, and may be in her peri-

neum; and in a great many women there have been a great many since, and will continue to be. After delivery of the child, there is delivery of the placenta by the expression method; and then a vaginal douche. This post-partum douche ends all. The ante-partum and post-partum douches are the only douches given.

Now I know very well that some of you practicing in healthy country districts are a little surprised that these douches should be used. The ante-partum douche I value more for saving the eyes of the babies, than I do for saving mothers. I am satisfied that in my own state of Pennsylvania, if every woman delivered in the next ten years should have an ante-partum douche of a one to two thousand mercury solution, it would reduce our blind asylums from ten to one; that ophthalmias would scarcely be heard of. My nurses at the Retreat are just as ignorant of ophthalmia as I am of leprosy. If you should visit that institution and ask an intelligent, painstaking, clean nurse, "Have you any opthalmia?" she would smile and say no; she could not answer your question, or if so she would answer it simply from her knowledge of what she had read. To demonstrate just what the ante-partum douche will do in saving eyes, I will call your attention to three cases—one delivered in the gutter before the house as she stepped from the carriage; another in the hallway on the way to the delivery room and the other while in the bath. There was no ante-partum douche in either of those cases and the three babies had ophthalmia. I know perfectly well while discussing this question, that many of you wonder at the occurrence of ophthalmia and post-partum troubles in a great city, when they never occur in your healthy agricultural districts; but let me say that they do occur in the healthy agricultural districts and in small towns. For instance, the wife of one of my acquintances in Johnstown was recently delivered, and the child was blind in three days. Now had this woman received a careful ante-partum douche and a careful toilet, this would not have been so. The man, the husband, had been unquestionably a victim of gonorrhœa and his wife was contaminated.

In dispensary work—in the alleys and courts of large cities—in railroad towns, the population is largely the victim of specific vices. In healthy rural districts it is not so. You can, as a rule put your finger on the contaminated woman or man in the agricultural districts. It is usually a young medical student, a drover or a drummer; but not among the clean, religious, spotless class of people. I know perfectly well, just as well as you do, from my intercourse with men of large experience and rare good judgment in the rural districts, that all this toilet is not necessary. For instance, I have friends in the valley of Virginia beginning at Winchester and running clear through to Staunton. A cousin of mine tells me that he has delivered fourteen hundred women and never had an ophthalmia, and yet he never gave the vaginal douche. There is Martinsburg, Winchester, Woodstock and other places where I have talked to the doctors in regard to such troubles, and they give me precise knowledge of their own work.

In dispensary work without douches, we have had a large number of ophthalmias. I know early in my own experience in dispensary work, I attended between 150 and 200 women every six months, and had great numbers of ophthalmia cases. Some of them lost their sight notwithstanding I used full strength solution of silver and other things. Taking the baby's head between my knees and going into the conjunctival sac and using a strong solution, I didn't succeed in saving all eyes. At present with seven or eight hundred cases to distribute among undergraduates, the instructions given to students are about as follows: The patient is advised when she applies for some one to take care of her in her confinement, to have her bedroom house-cleaned a few days before she expects to be sick; she is advised to take baths and to keep her bowels soluble. She is told she will be safer if she will have her bedroom house-cleaned a few days before she expects to be sick. We have a nurse that makes a visit to these persons, makes the toilet of the mother and child and goes on to the next patient. The student is told to take a syringe and some tablets or whatever he may be taught. The Jefferson student and the University student are taught very different stuff. He is told to practice what he is taught; to give the ante-partum douche and post-partum douche, and to give it himself; it will be

practice for him and do him good. He commonly gives the douche. He is told to use soap and brush thoroughly before and after each examination that he may make; that he may have the privilege of making examinations, auscultation and palpation and practice touch providing he uses the soap and brush freely; that the patient does not object to it and that she thinks he is painstaking and careful if he does examine frequently; and I make no objection *providing* he uses *soap* and *brush freely*. I find no mischief comes of it. This practical work is of great value to him; the care over five or six cases in the alleys and courts of a large city before he returns to a small town in Texas, Kansas or Tennessee, puts him at ease at his work when he gets home. And out of some 790 cases last year, in 780 there was not a single death from any form of post-puerperal or inflammatory mischief, no fevers, no chills or anything of that sort.

There is a great deal said in Germany about students examining. Some of the maternities take very high ground of recent years in regard to undergraduate work. The position is untenable. The rich have to take care of the poor. You will go into your own pocket books and into your own homes, towns and districts for that purpose; you must have something for it, and no harm can come from good honest work. The general mortality in puerperal fever is large throughout the country—no question about it. It remains large. In some small cities and towns where I have made careful inquiry, I discovered sometimes the mortality was very high. For instance the last eighteen or twenty months some seventy women have been reported in Scranton, Pa.—seventy deaths due to post-puerperal trouble; and in Paterson, N. J., in the last twenty months, some twenty women have died of puerperal fever; and within the last year in Philadelphia, in private work we have had a large number of puerperal fevers; for instance, one dying or dead within a square of my house—dying of puerperal fever. I saw her before leaving home.

Now in regard to irrigation and the use of the curette in post-puerperal troubles. In my own practice I have never had occasion to use either, either in Dispensary or Retreat or in private work. I have never used it except once or twice in intra-uterine irrigation; and I do believe that more mischief than good comes from intra-uterine tinkering. For instance a physician did a very thorough curetting and washed out the uterus, and the next day the patient had a chill and the temperature went to 105°. Now it is very curious that in many of these post-puerperal cases, the temperature goes very high after using the curette and intra-uterine douche. One case that I am referring to, the wife of a physician in our city, was confined during that excessive heated term, and on the third day had a high temperature and I am under the impression it was thermic fever; at the Retreat I had several cases of heat exhaustion. I hadn't a suspicion of post-puerperal trouble; I thought it was excessive heat; I thought they were all thermic fevers and I treated my cases as such and got good results. But on the fourth day they used a curette on this lady I refer to, and the following day she had a chill and her temperature went up to 105°. An additional consultant was called in, and he argued that probably the curetting was not sufficiently thorough and wanted to repeat it; and the use of the curette was repeated with a douche, and still her temperature remained high. Then they agreed to remove the uterus. After removing the uterus, they found a little puddle of muddy fluid in one of the sinuses. I naturally ask you did this little puddle of fluid follow the use of the curette, or did it antedate it? Did it follow the displacing of this clot or sealing this sinus, or did it antedate it? It is my impression that this puddle of muddy fluid, or pus fluid, followed the use of the curette and did not antedate it. Take the cases that you have now in bed—post-puerperal cases—and curette them all, and you will scrape away a lot of decidua vera that you may be pleased to call *debris*, and think that it ought not to be there. Not so; it ought to be there; it is so in every woman; it is a healthy dressing for the puerperal cavity. It should not be a *suspicion* or *guess* that there are some lurking or remaining membranes or placenta that induces you to curette her or douche her. It must be something more than that that makes you use the curette. It must be something *positive* and *definite* that warrants a procedure of that character, and I hold that simply a suspicion or a guess does not war-

rant it. I will say that my practice is not that of curetting or washing the cavity of the uterus where I am unable to put my fingers on something else.

DIRTY MIDWIFERY.

We all very well know that midwifery has never received that attention in private or public that it should receive. Many years ago, you probably remember, a lengthy discussion took place in Dublin, lasting some nine days, where they discussed pointedly the abolishing of the maternities. These were animated discussions indeed. And they did close the maternities all over the country, and from time to time continued to close them. The Queen Charlotte, of London, was closed a number of times on account of puerperal fever, for patients died in large numbers. The New York hospital maternities were closed and scrubbed out, and they tried it again. The Lying-in-Charity, of Philadelphia, and the old Lying-in-Charity of Pennsylvania hospital, were all closed for a time. The mortality ranged from five to some forty per cent. in the maternities. Now, we very well know that the very best work that is done on the face of the earth is done in maternities. When I took charge of the Preston Retreat—not that I wish to pat myself on the back, but I took charge of it to win—I saw no reason why a maternity should not be managed with a nil mortality, and I bent my efforts to that end. I have now delivered over twelve hundred women without a death from any cause, with that prolonged period of confinement of two weeks before and four weeks after, giving me of course a longer period for patients to die than that of any other maternity on the face of the earth, and I have not had a death of any patient either from eclampsia or any other cause. There has not been a death within the walls.

I have alluded to errors in plumbing. Just here I might refer to what takes place in tenement houses. I remember very well some years ago we had a number of tenement houses in the city—one on Front Street that we called the forty family house. The students used to come to me and say,—"Doctor, I have a patient who has had a chill to-day; I wish you would see her with me." I could name four or five houses in which this took place. With the patients who lived in alleys and courts with a cesspool in the rear of the court,—even in small houses, three rooms one above the other, three families in these three rooms — three families in a house—we rarely ever had trouble. Notwithstanding they did a general housekeeping in these three rooms, children sleeping on the floor and man wife in a small bed, it was exceptional to have any post-puerperal trouble in this illy-ventilated, dirty little room. But in the old tenement houses with the plumbing amidships, between the first, second, third and fourth floors, puerperal troubles always occurred. I made this statement five or six years ago in Newport, and it brought the distinguished obstetrician Lusk to his feet who said Dr. Price's statement corresponded precisely with his own observation; that he had made that observation frequently, and maintained that the plumbing frequently had much to do with post-puerperal mischief.

Night before last, when I left Philadelphia, I noticed behind me on the cars, three crying children. It troubled me. There was a distressed-looking man wrestling with these three children. The porter came by and I said—"Porter, is that man's wife dead?" He said—"I don't know, I'll find out." The porter got a glass of milk for the children, and made every effort to quiet them, and then asked the man if his wife was dead. He said—"Yes, she died three days after child-birth." That had as much to do with me taking part in the discussion as anything else; because I have discussed it so often that I sometimes think that I tire you, and some other subject would be much more welcomed; but I knew too well how exceedingly distressing this subject has become. I insist that hereafter the whole profession pay more practical and theoretical attention to this subject of paramount importance. We are all fathers and we should think more of the perils of child-birth and the care of tender mothers.

DR. DANNAKER: I would like to ask Dr. Price what covering the walls have in the Preston Retreat?

DR. PRICE: Paint only.

DR. DANNAKER: Not calcimine or whitewash?

DR. PRICE: No, sir; paint only. Just painted and washed.

Dr. Dannaker: Do you give the vaginal douche while she is taking the last bath ?

Dr. Price: There is no douche until she commences labor.

Dr. Dannaker: Do you have an inflow pipe in the room ?

Dr. Price: No, sir; tea-kettle in the delivery room; never leaves it. The delivery room is large and wide. On the bed there is just a clean hair mattress with a macintosh to cover it, and two clean blankets. She has her bath and her vaginal douche—glass douche-pan. This bath is outside of the delivery room. Before taking the bath an enema is given, and she evacuates the bowel before she enters the delivery room. The nurse makes her toilet—puts on a clean apron—makes her toilet entirely. She is not even allowed to keep her tooth-brush in the same mug with her hand-brush. I only allude to this to show you how far military discipline goes. It should exist in every hospital. If you can't have military discipline you don't have any discipline. I believe every doctor and surgeon should be a West Pointer for a while. It would do him good, particularly the surgeon and his assistant. I allow but few examinations; no washrags and no sponges; there is not a sponge or washrag to be found in the house, but we use corrosive jute—marine jute prepared chemically. You perhaps think I am *ultra* in my cleanliness or in recommending such a toilet, knowing, as some of you do, that I condemn all chemical solutions in surgery except for the purpose of obtaining cleanliness. Surgical cleanliness, if you can obtain it at any cost and by any means do so—chemically or by soap and water; but keep away from all surgery all irritating chemical solutions. For instance carbolic acid gives a variety of troubles. Mercury does pretty nearly the same thing. Carbolic acid gives you that numbness and tingling that is noticeable in sclerosis of the cord, and gives you a non-surgical hand as well. A mercury hand or carbolic hand is not safe from two points of view; being an irritating hand, and not being a perfect tactile hand. Chemical cleanliness in surgery or midwifery is the purest sort of cleanliness; hence I use corrosive jute. The sponge is exceedingly difficult to clean; it takes days or weeks to clean it properly. The surgeon only should clean his sponges, and nobody else. Corrosive jute is the cleanest material you can use.

Dr. Todd: Prepared by whom ?

Dr. Price: Prepared by Johnson and Johnson. It is nice and as soft as silk. You can make it into little washrags, and while the patient is in labor, a little washing about the vulva and about the bowel is all that is necessary. Now the delivery room contains two basins, two pitchers, scrubbing brush, tea-kettle and a gas stove. That is all. Those pitchers only leave the room to be filled with water, that is all. Those pitchers, tea-kettle and basins are used for no other purpose. Sometimes in private I feel at a loss for the simplicity of the delivery room; but you can have in private, just the same simplicity at little or no expense. For instance, the patients at the Retreat will change beds thrice. When admitted, a single hair mattress; when delivered, single straw mattress; when convalescent a wide hair mattress. Now you say you can't go to that trouble or expense in a small city. I think that is a mistske. A woman comes to you and asks you to take care of her during confinement, and probably she has a bed fifteen years old in her room. It will be a very simple matter to have three bundles of clean rye straw with a blanket folded over it, and a draw-sheet over that; that makes a good clean bed. Surely better than a bed saturated with urine. Perhaps one on which two children have died from scarlet fever or diphtheria. It is unsafe; it is contaminated and should not be used for childbirth. I know that some teachers condemn the straw bed. Parvin objects to it in a maternity. But you can buy one, or two, or three tons of clean rye straw, store it in a dry place and the beds can be made up and placed in a dry room, as dry and sweet as can be and will never become contaminated. We use as a cover simply a clean mackintosh with four thicknesses of blanket over it. I never allow anything to have a spot on it. The nurses are instructed to make their toilet before touching the patient, and to repeat that toilet before touching patient No. 2, and to repeat it again before touching patient No. 3. They are instructed to remove the draw-sheet and bed gown whenever it has a spot on it. Don't spare the laundry. There has always been a peculiar state of

affairs in maternities and hospitals that I can never understand, namely of sparing the laundry and laundry women and soap and water by changing sheets once or twice a week. Why, if forty times a day there is a spot on draw-sheet or bed gown, it must come off. And that holds precisely the same in the maternity as it does in my private hospital where I have to pay for it myself. And I think that we will all come to it after while, that we will have a Sunday morning laundry.

CORRESPONDENCE.

"INNOCENTS ABROAD."

EDITOR MEDICAL AND SURGICAL REPORTER:—I have been a subscriber of your journal for some years, during which time I have found few articles to criticise, but "Innocents Abroad" in the number of February 11th, I think is calculated to do a great deal of harm, inasmuch as it tries to make it appear ridiculous for a physician to visit Europe for post graduate work.

Now as I have had the pleasure of such instruction I cannot think it but producing a false impression that any such course in a European University is time wasted or that the American physician goes to Europe "to sit at the feet of some stupid privat-docent."

The great mistake is in any person going to a foreign university when he is not acquainted with the language spoken, and where his time could be better spent in New York, Chicago or Philadelphia.

Puffing at a meerschaum "unter den Linden" is not studying medicine.

During my stay in Prague in the Lying-in-Hospital, where in the two departments they have from forty to fifty births daily, I had advantages which are not to be had for money here, and the amount of fees paid in did not exceed twenty-five dollars.

The Rotunda in Dublin does not offer such obstetric advantages.

It seems to me that before any medical journal should pooh-pooh European Post Graduate courses, that they should furnish like advantages here.

The American people know a thing when they see it, and if the advantages there were not superior to our own they would not go that distance to procure them.

The writer of "Innocents Abroad" must know that neither the University of Pennsylvania, Jefferson, or Harvard, can furnish any such obstetric advantages as before described, and those given are monopolized and overrun.

A physician going to Europe if he knows where to apply, can get advantages not dreamed of in America.

Where in America can we find such a clinic for veneral and skin diseases as are furnished by Profs. Neumann and Kaposi, of Vienna?

The immense material for skin diseases, nose and throat, and surgery in Prague are not used by the foreigner, not on account of the names of Prof. Pick and Gussenhauer being unknown, but because so few know of the immense advantages offered in that city.

My advice to any German-American physician is first to practice a few years after graduating and then take post graduate work either in Prague, Vienna or Berlin, according to the advantages wanted.

If such a physician goes and uses his time properly, it will take a great many such articles as "Innocents Abroad" to make him believe that he has wasted his time, or that the same advantages could have been procured here.

O. C. STRICKLER, M. D.
New Ulm, Minn.

"Madam," said the doctor in answer to the earnest inquiry of his patient, "you are suffering from a complication of disorders, the exact nature of which can only be ascertained at the post-mortem."

"That is a very fine dog you have, Johnny."

"Yes, but he is consumptive."

"Consumptive! Why do you say that?"

"He's Spitz blood, you know."—*Ex.*

NEW YORK LETTER.*

At a recent meeting of the New York County Medical Society Dr. T. A. Emmet read a paper on "The Means of Success in Gynecological Plastic Surgery." He mentioned in the beginning, that while the fad for abdominal surgery had materialized a large number of expert laparotomists in this country, the skill requisite for plastic work had been almost lost. There is both lack of dexterity in operating and incorrect ideas of what is to be accomplished, hence many dismal failures result. In his paper he claimed that but one plastic operation should be undertaken at one sitting, and that many failures were due to the fact that two or three operations were performed at the same time. When only a single operation is done there is a much better chance of obtaining union by primary intention. He said the cause of the troublesome symptoms in laceration of the floor of the pelvis is a lack of support to the blood-vessels. Several years ago Dr. Emmet devised both the butterfly and the trefoil operations and he claimed that these, with the recent modifications he has added to them, will repair the damage; but that the dash-board-like obstruction put up at the vaginal outlet by some operators has not been successful. While he has always been able to repair any injury to the female genital tract, produced by usual causes, he has had much trouble in repairing those injuries left by poor surgery.

Dr. Emmet says that he owes his success in operations about the female genitals to the use of the silver-wire suture, which is not only a suture but a splint; nothing but silver wire should be used in plastic work about the vagina.

In the discussion that followed Professor Munde classified the essentials of success in plastic surgery about the female genital organs under the following heads: (1) Proper selection of cases. (2) Proper selection of time for operation. (3) Proper preparation of the parts. (4) Perfect asepsis including strict cleanliness, but avoidance of very strong germicides. (5) Rest, yet early movement of the bowels. Dr. Munde disagreed with Dr. Emmet in the necessary use of the silver-wire suture. He has employed with success, silk in the anterior vaginal wall and silk-worm gut in the perineum. He also said that more than one operation could be done at a time, and that he has often saved women much time, pain and expense by performing several operations at one sitting.

★ ★ ★

At a recent meeting at the Academy of Medicine, of the Section on Obstetrics, Dr. J. Harvie Dew read a paper describing his method of resuscitating still-born children. The method is original with Dr. Dew and because of it's simplicity has taken precedence of the harsher and more dangerous methods of Schultze and of Schroeder. Dr. Dew has employed the following method since 1871. He grasps the newly born babe with the left hand, the neck resting between the thumb and fore-finger, with the head falling far over backward, thus elevating and holding open the epiglottis by means of stretching the larynx and the trachea. The upper portion of the child's back rests in the palm of the hand; the other three fingers rest in the left axilla, raising the shoulder upward and outward. He grasps the right knee between the thumb and forefinger of the right hand, the left knee between the fore and middle finger of the same hand; thus the back of the thighs rest on the palm of the hand.

With the infant in this position the pelvis and lower extremities are depressed, and with the left hand the upper portion of the spine is greatly forced backward. This process draws down the diaphragm, thus enlarging the thoracic cavity and produces inspiration. Expiration is brought about by reversing these movements. The left hand carries the shoulder and chest forward and the right hand raises the pelvis and strongly presses the thighs against the abdomen. Thus the thoracic and abdominal viscera are forcibly crowded together, and a perfect expiration is executed. This process is repeated until the child breathes.

Although the process is powerful it can be produced without injury to the delicate tissues or viscera of the child.

The author of the paper said that many years of experience in the obstetrical field had proved to him that his method was

*Special Correspondent to MEDICAL AND SURGICAL REPORTER.

the most efficient and uncomplicated one of working articificial respiration. It is not tiresome to the operator, and can be kept up with the child immersed to the neck in water.

In the discussion which followed, Dr. G. T. Harrison said that he could truthfully vouch for the efficiency of Dr. Dew's method; that the process fulfilled the three indications in asphyxia of the child; it freed the air passages of mucous and whatever the child had inhaled in the way of foreign bodies; it carried air to and from the lungs, and it stimulated the movements of the heart. He said that the Schultze method was dangerous, particularly in the hands of a beginner or an awkward physician, as fractures, dislocations, and injuries to the thoracic and abdominal viscera often resulted from the violent handling of the child which the method necessitated.

Dr. Grandin said that he considered Dr. Dew's plan of very great value, and that he spoke from experience, having tested it in a large number of cases.

Professor Lusk stated that it was an excellent method and because of its simplicity and good results should be extensively practiced. He said that shortly after the child was born the use of a catheter to inflate the lungs was a good procedure.

The Hygienic Institute of the University of Berlin has published the following conclusions, after repeated experiments made with relation to the spread of the cholera germ through cigars and tobacco.

The comma bacilli of cholera Asiatica die through drying up on dried tobacco leaves even quicker than through drying up on glass, and in this condition they die in an hour on an average. On moist tobacco leaves the comma bacilli do not increase, and are killed after a short time. The comma bacilli were not proved to exist in the examples of cigars manufactured in Hamburg during the prevalence of the epidemic. Through the fermenting and drying processes which cigars must undergo before they are ready for shipment, the cholera bacilli are killed after a short time, even when packed by way of experiment in the linen bands about the cigars. Tobacco smoke checks the development of cholera bacilli and is quickly fatal to them.—*Phar. Era.*

Cuneihysterectomie—A New Operation for Flexions of the Uterus.*

Thiriar reports a case of a cure of anteflexed uterus by operation under the above name. Having borrowed the idea from the operation of Osteotomie for genu-valgum. After opening the abdomen he draws up the uterus, then resects an elliptical portion, 2 cm. in width, which extends down through the muscular structure of the uterus to, but not into, the mucous membrane. This section is removed at the point of flexion. The uterine wound is sewed with catgut and the abdomen closed. An iodoform tampon is placed into the vagina, presumably, to hold the uterus in position, until the cure is established. Thiriar has reported his case as having remained cured for two months after which he lost sight of her. [This certainly seems to us a heroic measure for the relief of an anteflexed displaced uterus. It would be interesting to know the future history of such a patient including a possible pregnancy.—Ed.]—*Annal. de gynécol.*, 1892. Oct. p. 26.

A Costa Rican Costume.

The doctor, the author, the farmer and I were talking of travel in far foreign lands, the most entrancing topic of conversation on earth, and the doctor told this story:—

In the Spanish American countries, it is customary for servants and young people to go about in the hot weather almost naked, though they usually wear hats on account of the glaring sun.

One day a Costa Rica grocer sent his boy to deliver some goods purchased by a family newly arrived from more inclement latitudes. The boy was wearing a sore toe and a brunette smile. When he returned he brought the grocer a note, vigorously objecting to his attire or lack of it.

"Caramba!" said the grocer sternly. "You young villain, don't you ever go to that house again without putting on your hat!"—*Ex.*

Patient—"Doctor, let me know the worst."

Doctor—(absent mindedly)—"Your bill will be two hundred dollars."

EDITORIAL.

THE REDUCTIO AD ABSURDUM.

DEPARTMENT OF PUBLIC CHARITIES.
PHILADELPHIA, March 2, 1893.

To the Board of Management of the State Hospital for Insane for the Southeastern District of Pennsyluania:

Gentlemen:—At a meeting of the Board of Public Charities of the Commonwealth of Pennsylvania, held yesterday in Harrisburgh, the following preamble and resolutions were unanimously adopted:

WHEREAS, This Board at its meeting in December last considered a report presented to it by the Chairman of the Committee on Lunacy, and authorized its transmittal to the Board of Management of the State Hospital for Insane for the Southeastern District of Pennsylvania, and

WHEREAS, It is evident that that portion of the report setting forth that the management of said hospital were permitting surgical operations of an experimental nature to be made upon their patients is incorrect, and based upon erroneous information, and

WHEREAS, No surgical operations of such character have either been performed or proposed at this Institution, therefore be it

Resolved, That the Board hereby withdraws said report transmitted as aforesaid, and further

Resolved, That, as the said report was made public without its sanction, this Board waives any objections to the management of the Norristown Hospital making public these resolutions in any manner they may deem proper.

Yours very respectfully,
CADWALADER BIDDLE,
General Agent and Secretary.

These resolutions which are in answer to a communication from the Board of Trustees of the State Hospital for the Insane, at Norristown (given in full in the last issue of THE REPORTER), command respect and admiration.

Perhaps it is not infrequent for such a body as the State Board of Charities to find out that they have made an error, but it certainly is rare for such a body of men, after being misled by their own agents, to frankly acknowledge their mistake, and so speedily to rectify it.

The State Board of Charities deserves the fullest commendation for this last action. Their communication is a digni-

fied acknowledgment of an error committed, an honest expression of regret, and a prompt rescinding of an injudicious action. It is more. It is an indignant repudiation of the men who misled them, and the methods by which they were deceived.

It can readily be understood how the Board were led into this action by their Committee on Lunacy, when it is remembered that the Board is compelled to rely largely upon its professional members for opinions on technical questions. This fixes the responsibility upon the Committee on Lunacy. Fortunately for some members of the Committee on Lunacy the responsibility can be narrowed down still further. Three of the five members of the Committee supported the passage of the above resolutions; the other two—the professional experts— were too busy to attend the last meeting of the Board, after finding that body not disposed to "quietly drop the matter." This fixes the responsibility upon the professional experts.

A typical *reductio ad absurdum.*

The serious side of the question being thus disposed of, leaves only the amusing for contemplation, and as it would be unfortunate for the cause of Professional Philanthrophy to allow the arduous labors of the Professional Reformers to be utterly lost, the following suggestions are offered for future guidance:

Nations and tribes of men differ in their treatment of the insane in so much as they differ in civilization. In some parts of Africa they dispose of the question *cito, tuto et jucunde.* When one becomes old, feeble or insane loving hands carry her out and deposit her in a convenient place to become food for wild beasts. The state or tribe is thus spared any expense and the consciences of philanthropic lawyers are not rasped by *cruel operations.*

In Australia, among the natives if a lunatic becomes troublesome they simply go into executive session, and knock him, her or it in the head with a club. The question as to whether insanity is a disease or the result of disease is not entered into at all. The remedy is a specific for all forms of mental alienation. Pathology is ignored, prognosis is assured and treatment is routine enough to satisfy any committee on lunacy or its legal members. If these patients have tubes or ovaries tender, inflamed, adherent, degenerated, metamorphosed or decomposed "allee samee Melican man," they can keep them.

They never raise the question of objectionable mutilation after recovery.

The "legal member" has given his august opinion that neither a patient, nor her guardian or relative can give consent to such an operation, for fear that she might be cured and then object to her mutilation.

What is to be done with our insane friends if this dictum of Dogberry holds good? The rule will apply to any other form of disease and, as no surgeon will be permitted to operate without the consen of some responsible person, and no one can by law give his consent, there is but one thing left to be done.

Philanthropists will have to furnish the "legal member" or some other professional humanitarian with a good large club, and turning him loose among these unfortunates, let him treat them after the Australian plan. Everything will then be lovely, all expenses to the state be saved, and the "l. m." become the hero of his dreams.

A physician's library and instruments are exempt from execution. The insurance on the same is also exempt. So says a recent Supreme Court decision.—*Ex.*

Bellows—I don't believe you are anything of a doctor.

Dr. Surekill—Just ask my patients.

Bellows—I don't speak the dead languages.

TRANSLATIONS.

THE TREATMENT OF DIPHTHERITIC ANGINA BY CHROMIC ACID.†

Lescure (*Jour. de Mèd. de Paris*, Feb. 12, 1893) remarks that it is now clearly proven that the infectious manifestations of diphtheria are due, not to the invasion of the organism by the bacilli—even in the most rapidly fatal cases they are not found in the blood—but to the absorption of a toxine of peculiar virulence, secreted by the bacilli, which quickly spreads throughout the entire organism. The problem, therefore, reduces itself to the destruction of the false membrane (that is to say, the laboratory whence the microbe launches into the circulation the fatal toxines) before a sufficient dose to cause death has penetrated into the economy; this is the local treatment. As this dose ought evidently to vary with the resistance of the subject, it is necessary at the same time to increase this resistance; this is the general treatment. In other words, the treatment should fill two indications: 1. To destroy the false membrane, that is to say, to prevent the production of the toxines, *as quickly as possible;* 2. To combat the effects produced upon the system by the toxines which have already entered the circulation at the time of intervention.

Destruction of the false membrane may be accomplished by touching it with a solution of chromic acid, 40 to 100, repeating this once, twice, and very rarely three times in the twenty-four hours, according to the gravity of the case. At the same time the adjoining mucous membrane should be sterilized by painting it with tannic acid, six grammes to thirty of glycerine, repeated three or four times in twenty-four hours. At the same time also, the tincture of eucalyptus should be administered in three to ten gramme doses in the twenty-four hours according to the age. The general treatment consists of alcohol, nux vomica, quinine, milk, coffee, tea, suralimentation and oxygenation.

DESTRUCTION OF THE FALSE MEMBRANE, OPERATIVE TECHNIQUE.

The physician should supply himself with a caustic solution of chromic acid, 40 to 100. The application of weaker solutions is without result. The child, enveloped in a blanket, the arms extended on the body, is seated upon the knees of an assistant who faces the operator, and with his right arm supports the child, while with his left hand he supports the brow, immobilizes the head and holds it against his heart. On a table or chair to the right hand of the operator are placed: 1. A saucer containing some drops of the chromic acid solution and a small stick; 2. A glass half full of a soapy coal-tar solution diluted with water and containing a charpie mop. With the left hand the tongue depressor is introduced into the mouth of the child and pressed upon the base of the tongue. There is thus obtained a sufficient depression of the lower jaw to permit of easy exploration of the posterior pharynx. The mop charged with two or three drops only of the chromic acid solution is taken in the right hand and the false membrane is touched rapidly and lightly in order to avoid the healthy mucous membrane. The yellow coloration of the coated surface indicates that the application has been sufficient. This operation need not consume more than three or four seconds. The tongue depressor is now cleansed and the mucous membrane is matted out with the coal-tar solution two or three times. This neutralizes the excess of acid, and also has another action. The liquid uniting with the excess of acid forms a diluted solution which has a styptic action, and which produces around and upon the false membrane an albuminous precipitate which should carry with it a large portion of the toxic substance secreted by the bacilli and covering the mucosa. In the light cases, taken at the beginning when the false membrane has as yet but slight degree of thickness, one or two operations usually suffice to destroy it. In grave diphtheria it is necessary to renew the treatment several times; but rarely are more than three applications required in the twenty-four hours. In every case it is necessary to repeat them until the false membranes have disappeared. Under the influence of this treatment the false mem-

†Translated for The Medical and Surgical Reporter by W. A. N. Dorland, M. D.

brane does not disintegrate, but on the contrary it condenses, contracts, diminishes in extent, disappearing at the edges, and ends by coming off in one piece without leaving a subjacent wound, during one of the applications of tannin.

This employment of chromic acid in a dose so concentrated may seem daring to the first degree; nevertheless, it is exempt from all danger, and Lescure has employed it exclusively for five months without any disastrous consequences. This is explained by the valuable property possessed by this acid of not extending its action superficially beyond the point of application, and in depth beyond the thickness of the layer of liquid applied. Moreover, eminent practitioners such as Magitot and Isembert, have used it successfully in affections of the mouth, and even have applied it to the larynx. It should undoubtedly be used with prudence and the applications made lightly, but by employing only the quantity of acid strictly required no danger will be done to the neighboring tissues.

STERILIZATION OF THE SURROUNDING FIELD.

For this purpose a glycerole of tannic acid may be employed, six grammes of tannin to twenty grammes of glycerine. Three or four paintings are made in the twenty-four hours, only one of which is made during the night. As an adjuvant to the direct sterilization obtained by this method, the tincture of eucalyptus may be given internally, three to ten grammes daily according to the age. This agent is eliminated largely by the mucous membranes, and by giving it in repeated doses every second hour its exhalation by the respiration is continuous as shown by the odor of the breath, and consequently the bronchial, tracheal, laryngeal and pharyngeal mucous membranes are constantly bathed in a material which not only is hostile to the multiplication of the bacilli and the propagation of the false membranes, but which also hinders the absorption of the toxines.

General Treatment.—The general treatment comprises two indications: 1. To sustain the general state of the patient so as to combat the poisoning; 2. To facilitate the destruction and elimination of the toxic products already absorbed. To meet the first indication an alimentation at once reparative and light; must be insisted upon; bouillon, broths, beef juice, eggs, chocolate, purees, creams; at the same time the asthenia is met with nux vomica, quinine, alcohol, Bordeaux wine, Malaga wine, cognac, or rum, from thirty to sixty grammes in the twenty-four hours. To facilitate elimination of the toxic products by the renal emunctory, milk, coffee, tea, are given to the child, and in these the cognac or rum is given. Finally, the combustion of toxines in the blood is facilitated by increasing the quantity of oxygen absorbed, and for this purpose the most thorough ventilation possible is insisted upon, all the windows being opened to permit the rays of the sun to enter. Experience has shown the valuable effects of this practice.

Formulæ:—

℞ Acid Cromic..... ..2 grammes.
Distilled Water.....5 "

℞ Tannic Acid..... 6 grammes.
Glycerine.....30 "

℞ Tinct. Eucalyptus.....3 to 10 grammes.
Gum Arabic Water.....90 "
Syrup of orange peel.....30 "
To take in teaspoonful doses in the twenty-four hours.

℞ Tinct. of Nux Vom..... *x* drops.
Ext. of Quinine ..... 5 grammes.
Malaga Wine.....200 "
Syrup of orange peel.....100 "
Three tablespoonfuls in a day.

The tincture of nux vomica should be given in such a way as to give the child at least three drops in the twenty-four hours. This dose may be raised to five, six or eight drops according to the age.

Results:—The number of cases treated to date by Lescure is fifty-four. He has not had a death. Among the fifty-four cases, five presented the characteristics of hypertoxic or rather infectious diphtheria, the diphtheric bacilli and the pyogenic streptococci of Barbier being mixed. The false membranes were soft and very thick, of a pale color, face swollen and livid, enlargement of the glands and edematous enlargement of the neck, fetid breath, severe pain, intense fever, albumin in the urine, somnolence, a very pronounced general asthenic state. The patients were twenty-seven months, three years (two), four years, and seven years of age. The duration of the sickness was from nine to fifteen days.

ADVANTAGES OF THE TREATMENT.

1. *The rare intervention and short duration of each application.*—The applications of chromic acid are only needed

once or twice in the twenty-four hours, and the paintings with tannic acid only three or four times. The applications therefore, are made only every three or four hours at the most. This permits the saving of the forces of the child and permits it to sleep.

2. *Absence of pain.*—This treatment is absolutely painless and does not determine any inflammatory reaction in the throat.

3. *The integrity of the mucous membrane is absolutely guarded.*—The false membrane in falling off under this method of treatment does no leave any raw patches which may act as ports of entrance for the poisonous products.

4. *Finally this treatment is very easy of application.*—While the applications should always be made by the physician himself, as generally there are only one or two in the twenty-four hours this can readily be satisfactorily arranged.

ABSTRACTS.

A FEW PLAIN WORDS ON GLAUCOMA.

The relatively large number of cases of absolute and hopeless blindness from neglected glaucoma coming under my observation, writes Dr. Lewis, of Raleigh, N. C., has suggested to me the propriety of making an effort to do something in the way of prevention of such sad occurrences. Blindness from this cause is peculiarly deplorable for the reason that the afflicted one is not only cut off from all perception of light—even a deprivation that only the blind that retain the power of discriminating between day and night can fully appreciate—but is a sufferer, in many instances, from repeated and long-continued attacks of severest pain.

For our purpose it would be best to consider only the three ordinary forms of the simple or chronic, the subacute and the acute inflammatory. The symptoms common to all forms are failure of sight, increased tension or hardness of the eyeball, dilated pupil, and contraction of the visual field especially toward the nose. The most characteristic of these is increased tension, which is to be ascertained by gently palpating the globe through the upper lid as the patient looks at his feet, very much in the same way as for pus in a suspected abscess. If not familiar with the feeling of the normal eye, a comparison should be made with the other eye, if unaffected, or with the examiner's own. The next most important symptom is dilatation of the pupil, particularly if it does not respond to light. A fact of great assistance in a negative way, in helping to a correct diagnosis, is that the subject of glaucoma is almost sure to be past middle age, or old enough to wear spectacles for reading. And the first thing one suffering from chronic glaucoma, as a rule, notices is that his spectacles do not suit him as well as they once did, and that he cannot find any that will bring his sight up to the original standard. The need of frequent changes in his glasses is often a premonitory sign. He will then complain that at times there is a fog or haze over his sight, lasting for a greater or less period and then passing off entirely for a while, only, however, to return again at shorter intervals, denser in character and hanging over him longer. While this fog is present he will tell you, usually, that when he looks at a lamp or other light it seems to be surrounded by colored rings haloes or rainbows—a phenomenon only found in glaucoma, except when produced by mucous on the cornea, which can be easily removed by winking. Pain, if present at all, will be slight and occasional. A superficial inspection of the eye will show the sclerotic white, the cornea clear and bright, and, in a word, the eye perfectly normal in appearance, save a slight dilatation and some sluggishness of the pupil. The tension will probably be a little increased, and the field of the vision somewhat narrowed.

In the subacute form, after, in all likelihood, a few premonitory attacks embodying the symptoms just enumerated as belonging to the chronic, there will be a more rapid failure of sight—pain in, but chiefly around, the eye, over the brow, in the temple, down the side of the nose, and, sometimes, all over the side of the

head, will be complained of—the globe will be very distinctly hard—there will be some redness of the ball, or rather dusky character, most marked just behind the sclero-corneal junction—the cornea will look rather steamy—the anterior chamber will generally appear shallow, the pupil will be dilated and probable oval in shape, and, instead of being black, it will be of a yellowish green color.

The acute form is simply an exaggeration of the subacute. The onset is more rapid—the tension greater—the pain more severe—the redness more intense, in some instances extending to the whole conjunctive with a swelling of the lids—occasionally there is a photophobia—the pupil is more widely dilated, though not necessarily *ad maximum*, and fixed—the cornea looks more hazy and insensible to the touch of a light, soft object, as a feather or wisp of tissue paper—and sometimes there is fever with nausea and vomiting. Inasmuch as the mistake has been made, I will take the liberty of saying that should you have a case of supposed remittent fever, who, at the same time, has had a bad eye, do not be satisfied with your diagnosis until all doubt as to the nature of the ocular trouble is removed, and *do not wait for him to recover from the fever, or "bilious attack," before attending to his eye.*

The diseases with which inflammatory glaucoma might be confounded are iritis, conjunctivitis, cataract, inflammation of the cornea, and neuralgia. There are many resemblances between acute iritis and acute glaucoma, and there are many differences, but the similar features, unfortunately, are of a coarser and more easily recognized character than the dissimilar. In order to avoid confusion, I will rest the differential on two symptoms, or signs, only—the state of tension and of the pupil. While in iritis the tension is sometimes increased, it amounts to practically nothing, but in glaucoma it is the pathognomonic symptom, and in the inflammatory form—with which alone iritis could be confounded—it is almost certain to be very distinct and pronounced. The pupil in iritis, if changed at all in size, is smaller than the normal, but in glaucoma it is almost invariably larger than natural, and, in an immense majority of cases, very much larger. If in doubt compare with sound eye, should there be one or with a healthy eye in another individual of about the same age and in the same light. Never fail, therefore, to examine more carefully the pupil in every red eye belonging to an elderly person, and particular if that eye be free from a mucopurulent or purulent discharge—the presence of this discharge being the characteristic symptom of conjunctivitis.

In conjunctivitis the redness of the globe increases from before backward, while in glaucoma, as well as in iritis just the reverse is true. In conjunctivitis, too, the sight is scarcely, if at all, impaired —in glaucoma it is apt to be very bad.

It is of vital importance that glaucoma and iritis should not be confounded with one another, for the remedy appropriate to each is generally positively injurious to the other, in some cases actually exciting an attack in a healthy eye predisposed to that particular affection. If the pupil be carefully examined and its size noted the mistake in the application of remedies could not well be made, for it is the most elementary common sense, it seems to me, for every one using remedies directed to the pupil to attempt to contract a pupil that is too large and to dilate one that is too small. Attention to this simple rule would insure practically the use of a myotic, eserine sulphate or pilocarpine muriate, in glaucoma, and a mydriatic, atropia sulphate, in iritis.

Having made the diagnosis of glaucoma its early management is very simple. It consists in the *immediate* use locally of a myotic, sulphate of eserine, a drop or two of a solution of a strength varying from one to four grains to the ounce, or pilocarpine of double that strength, in the eye every hour until the pupil contracts, pain is relieved and sight improved, and continued afterwards three or four times a day until the trouble has passed off. Hot applications, purgatives, hypodermic injections of pilocarpine, etc., are sometimes helpful, but such uncertain palliatives should not be depended on, except only when nothing better can be done. Should the pupil not respond to the myotic and a marked alleviation of the symptoms occur in twenty-four hours, or if its use increase the pain and inflammation, as it sometimes does, an iridectomy or sclerotomy, preferably the former, in my opinion, should be done at the earliest possible moment. Acute glaucoma is a disease

that allows no dallying in its treatment—the price of sight is *promptness*—and, eserine or pilocarpine failing, the knife is the only hope.—*Charlotte Med. Jour.*

THREE CASES OF PUERPERAL ECLAMPSIA.

Dr. John Marriott reports three cases:

Case 1. June 2d, 1890. Patient aged 39, a XI para. The author was told that she had ten violent fits during the night and had not spoken for hours. He found her in deep coma and tongue badly bitten. Cyanosis was extreme and she breathed with difficulty. The pulse was feeble and intermittent. Urine drawn by catheter proved to be highly albuminous. There was no sign of commencing labor As she immediately afterwards had two more fits and was evidently in a desperate condition, the author proceeded to attempt delivery. The os was fortunately soft and yielded to digital dilatation so that in about twenty minutes he was able to turn, and in about another quarter of an hour both child and placenta had been expelled. The patient flooded violently and, unfortunately, the author had no ergotine with him and she could not swallow. The hemorrhage was arrested by hot water injection. The child did well. The mother lay in deep coma for several hours, but had no more fiits. She recovered without a bad symptom. After a few days the urine was found to contain no trace of albumen. She has remained in good health ever since, earning her living as a washer-woman.

Case 2. August 29, 1891. The patient, aged 21, had five fits in two hours. She had been ailing for some weeks, anemic and suffering from dyspnœa, but her condition was not suspected. The author found her unconscious with a portion of the tongue bitten clean out. Finding the vulva œdematous and the legs slightly so, he drew off the urine and found it nearly solid with albumen. She appeared to be about four months pregnant and the fœtal movements were perceptible. Soon afterwards she had another fit during which respiration ceased and was with difficulty re-established. He placed two drops of croton oil on the tongue and administered a little chloroform, proceeding then to dilate the os with the finger. The cervix was long and very rigid, but in nearly an hour he succeeded in introducing six laminaria tents. After this she had no more convulsions, but came round sufficiently to a full dose of chloral. The oil acted vigorously and labor pains came on regularly. When the tents had been in twelve hours the author removed them and the fœtus immediately followed. There was no difficulty with the placenta and no hemorrhage. She had complained much of headache and giddiness for the last two hours, but was quite conscious. About ten minutes after the birth of the fœtus she was suddenly seized with violent dyspnœa, which lasted about a quarter of an hour. There were no abnormal physical signs to be discovered in the thorax. She had several of these attacks during the next few days, but less severe. They seemed to be uræmic in nature. The urine continued albuminous and she had bad headache for sometime. She also developed a rough systolic murmur at the left apex, evidently caused by dilatation of the ventricle as the apex became displaced downwards and outwards. The pulse showed increased tension, and the œdema of the vulva and legs remained stationary for quite a fortnight, after which it slowly declined. The endocardial murmur slowly disappeared, and the albumen decreased *pari passu* with the general improvement.

Case 3. October 3, 1891. The patient was an extremely pale, thin woman, aged 38, of a phthisical family and never enjoying good health. She had ten children, subsequently two miscarriages. On the morning of October 3rd—she had a fit, and soon afterwards had three more without regaining consciousness. The author found her quite blind and only feebly conscious on his arrival at 8.30. She made some attempt to speak, but was incoherent and groaned often as if in pain. She also resisted being moved or touched. Almost immediately she had another fit, which began with conjugate deviation of the head and eyes to the left and complete arrest of respiration, the whole body

becoming perfectly rigid. In about fifteen seconds violent clonic spasms succeeded, affecting the whole body simultaneously. These continued with unabated strength for about forty-five seconds and then suddenly ceased. Breathing was extremely shallow and sighing, and the patient much cyanosed. From this point she gave no sign of consciousness and could not be roused. The author found the urine highly albuminous and so at once commenced digital dilatation of the os. Being constantly interrupted by fits he gave a small quantity of chloroform at intervals in the hope of moderating their violence, but it did not appear to have much effect. He found the os very rigid, as it had not been fully dilated for four years. Consequently he was only able to get it to admit three fingers and to rupture the membrane. On returning three hours later the author found that no progress had been made. She had had numerous fits and was obviously in a critical condition, the breathing being of marked Cheyne-Stokes' type; the pulse imperceptible at the wrist, extremities cold and the larynx much obstructed with mucous, which she made no effort to dislodge. There was no return of consciousness. As a last resource the author attempted to apply the forceps through the half dilated os, and on getting them fixed injected hyperdermically a full dose of ergotinin and a minim of liquor strychninæ. The fœtus, though near term, was very small and was extracted in a few minutes. The patient's condition was so critical that he was obliged, just before the birth of the child, to inject two syringefuls of brandy under the skin of the abdomen. He waited nearly half an hour before attempting to remove the placenta, knowing the patient's tendency to flood, but the uterus contracted firmly and gave no trouble whatever. She had two more convulsions between the delivery of the fœtus and placenta, not so severe as those preceding, and after the expulsion of the placenta there was absolutely no recurrence. She remained unconscious for about eight hours, but swallowed small quantities of brandy and milk when poured into the back of the throat. Later she fell into a natural sleep. Suppuration followed in the track of the injections of brandy, but not in that of the ergotinin. She made excellent recovery, but the fœtus was dead. A week after delivery there was no trace of albumen in the urine, but the urea was deficient being only .07 per cent.—*Lon. Lan.*

CURRENT LITERATURE REVIEWED.

THE MEDICAL CHRONICLE

of Manchester, England, for February contains an interesting paper by Dr. Thomas Harris on "Some Clinical and Post-mortem Observations on the Cardiac Dullness in Cases of Mitral Disease, and on the Relative Size and Position of the Cavities of the Heart." The different points discussed by the author are illustrated by reports of cases, and also by diagrams of the area of dullness over the cardiac region in the several cases.

Dr. W. Roger Williams continues his communication on

Observations on the General Pathology of Cancer—Especially of the Breast,

this number being devoted to the prevalence of cancer and its increase. "Cancer," he says, "has steadily increased during the last half century and is still increasing, and this in spite of diminution in the general death rate. Insanity also is on the increase." This statement he fortifies by tables from the office of the Registrar General for the years 1838 to 1890 inclusive, and also the death rate from cancer in other countries. "The augmented cancer mortality has coincided with progressive population, increased national wealth and marked improvement in the general well-being." It is impossible to consider this in any other light than cause and effect. The author also points out the decline in the death rate from phthisis and other tubercular diseases, which decline he regards as due to improved hygienic conditions and the very causes which have increased the can cer mortality.

Dr. Ernest S. Reynolds considers the causation of the deep reflexes (knee jerk, etc.) which he terms "Myotatic Contractions." He sums up as follows: "In the production of myotatic contractions, although the direct increase of tension by tapping the muscle or its tendon is probably the best way of inducing the phenomena, yet that in many cases, this increase can be caused very directly by the physical diffusion of vibration transmitted even from a distant part of the body." The contractions he thinks are not true reflex actions but are due to an increased tension of muscles in a state of myotatic irritability.

In the "Clinic" department Dr. W. H. Brazil reports a "Case of Gunshot wound of the Abdomen; Operation; Recovery." The

bowel was perforated by the ball in four places which were closed with Lembert sutures of catgut. The case recovered promptly, with no complications except a small fæcal fistula which quickly closed.

Dr. W. Roger Williams reports a case of

Laparotomy, with Excision of the Appendix, For Acute Perforative Appendicitis.

The patient presented symptoms of appendicitis; constipation, dullness and pain in the right flank, though the principal tenderness was in the left iliac region, and at no time was it possible to detect any tumor in the region of the appendix. At the operation the appendix was found enlarged and with a perforation at its apex. In the pelvis at the position of the apex of the appendix, there was a collection of pus the size of an orange. On opening the appendix a fæcal concretion the size of a date stone was found. The patient survived the operation six hours.

Severe Crush of the Chest.

A case is reported by Dr. J. M. Crawshaw, as the result of the patient having been crushed between two carts. On admission to the hospital the patient was suffering severely from shock and complained of great pain over the sternum and the left side of the back. It was impossible to feel the ribs, owing to the extensive emphysema present, which increased until it extended from the temporal regions of the scalp down to the wrists and to within three inches of the angles. The patient survived eight days. At the post-mortem the first six ribs on the left side were found fractured, the first through the neck, the lower ones through the angles. There was a tear in the parietal layer of the pleura above the first rib. The left lung was collapsed, solid, with two large ruptures in its upper lobe. The right lung was unimpaired. Two unusual features about the case were the slight amount of hæmoptisis and the fracture of the first rib without the clavicle being broken as well.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

for March contains a paper by Dr. S. Weir Mitchell on

Hysterical Rapid Respiration, with Cases; Peculiar form of Rupial Skin Disease in an Hysterical Woman.

The form of breathing is largely upper costal, sometimes exclusively so, and as a rule slight in amount. Early in the case the patient is ignorant of the existence of the symptom, but later, when the attention is called to it, the respiration rate is increased by any excitement—as the approach of nurse or doctor. Usually it is absent in sleep and the type of breathing is quite impossible as the result of voluntary effort. The paper gives the report of the cases in full and the tracings of the respirations are contrasted with the attempt of a healthy man to simulate rapid breathing. The rupial affection occurred in an hysterical girl and was pronounced by Dr. Duhring to be due to a degeneration of the nervous system. It was not syphilitic nor sarcomatous, but due to the disturbed state of the whole nervous system.

Dr. George H. Edebohls contributes a paper on

Movable Kidney; with a Report of Twelve Cases Treated by Nephrorrhaphy.

The author states that he believes the disease to be more common than is usually supposed, stating that out of 500 women examined he found it to exist in 90. Not every movable kidney however produces symptoms and often the possessor is not aware of his ownership. The author's theory as to its causation is the absorption or atrophy of the peri-renal fat. The subject is of interest to the gynecologist on account of its frequency in women as compared with men, and also because its symptoms are so similar to those accompanying lesions of the genital organs. Its frequency in women may, however, be overestimated on account of abdominal palpation being more frequently practiced on women than on men. In the majority of cases it occurs on the right side though Dr. Edebohls has seen it also on the left. Why it should occur on one side more than on the other he is unable to say. Perhaps the right kidney is more exposed to displacements on account of its position immediately below the liver, a heavy organ subject to great fluctuations in size and weight. "The morbid phenomena due to a movable right kidney in its earlier stages are digestive disturbances, chronic in character; general nervousness; epigastric pain, usually located somewhat to the left of the median line, at or near the free border of the left costal cartilages; cardiac palpitation; inability to feel comfortable or to sleep when lying on the left side." The diagnosis is easy and is made by the discovery of a movable tumor of the size, shape and consistency of the kidney, in the right hypochondriac or lumbar regions, or in the iliac fossa. In the treatment, a bandage is generally recommended, but the author thinks it ranks a poor second to nephorrhaphy. A well-fitting, rather tight corset answers well in males, and in women in whom no contra-indication exists in the condition of the sexual organs. The paper is to be continued in the next issue of the journal.

Dr. H. Augustus Wilson discusses "Fixation after Excision of the Knee." After reviewing the literature on the subject the author presents the following conclusions: Metallic bone-sutures will secure the most efficient internal approximation. They should never be removed unless some serious condition demands it. The entire leg should be kept free from the patient's control by an external splint for from four to six weeks. The most important element in the treatment is the prolonged use of a rigid brace.

Dr. Norman Bridge in a

Note on a usually overlooked condition in the Grave Convulsions of Infancy and Childhood,

divides the seisures into two classes. One is a true epileptic seizure, coming on suddenly without apparent accompanying illness, and provoked by some slight physiological disturbance, such as indigestion. In the other

form the fit is prolonged, a true eclampsia. The most notable difference clinically, is the presence of high fever (102° to 108° F.) in the eclamptic form. In the treatment cool bathing is advocated, especially as the temperature is reduced by this means. Of drugs he regards hydrate of chloral as the one most useful. Next comes opium. The bromides are useless.

In an article on "Cocaine in the treatment of Variolous and Varioloid Infection," Dr. Edward Pepper strongly advocates the use of this agent; stating, that by its use variolous and varioloid poisoning can frequently be arrested in a marked degree.

Dr. Henry J. Garrigues reports a successful case of "Symphysiotomy" illustrating the paper with cuts of instruments used, and photographs of deformed pelves.

Other papers in this month's issue are "A question of "Water, Ethics, and Bacteria," by Albert R. Leeds, Ph. D. The question of water analysis is entered into and discussed together with the best means of purifying the drinking supply of a large city. Dr. F. X. Dercum reports "Two Cases of Akromegaly," with remarks on the pathology of the affection. The report is illustrated with photographs of the patients.

THE AMERICAN JOURNAL OF OPHTHALMOLOGY

For January contains a long letter from Dr. Swan M. Burnett, of Washington, in reply to one by Dr. A. E. Davis, in the *N. Y. Med. Jour*, for November 19th, 1892, under the heading of "Ophthalmometry in America."

The answer is in a good humored but decidedly caustic strain. It would seem that the energy expended in a mere priority fracus could be utilized with some profit in other ways. Surely the space thus wasted could have been filled with matter of some benefit to the profession.

"Two cases of Gonorrhœal Iritis" are reported by Dr. Adolf Alt.

There is also a translation of a clinical lecture by Prof. Panas upon

"Sympathetic Ophthalmia."

Reference is made in it to the experiments of Leber and Deutchmann by which they claimed that the inflammation was propogated from one eye to the other by the optic tract. Panas proceeds to say "But these experiments have been done many times since, and the results are not at all sure, so that we must not accept his theory as proved. At the last congress at Heidelberg, Schmidt, Pflueger, Lagneur and others spoke against it. If we cannot accept this theory, we cannot admit the advisability of an operation or attempt to prevent sympathetic ophtholmia by section of the optic nerve, or resection combined with abrasion of the ciliary nerves and vessels. We can add that this operation often results in an hæmatoma of the orbit, marked protusion of the globe, and death by meningitis, and that this happens much more often than has been said or written." The writer considers enucleation the most reliable means of preventing sympathetic ophthalmia. He also employs mercurial treatment either by "rubbing the ointment into the eye, or by hypodermic injections."

THE BRITISH JOURNAL OF DERMATOLOGY.

The February number contains two articles.

Dr. Alfred Francis in a paper on

Lymphangioma Circumscriptum Cutis

proposes (1) to describe the cases which have come under his own observation and some others, and (2) to attempt to group the recorded cases, basing their classification partly on their anatomical and partly on their clinical features. Though they all appear closely allied yet, for descriptive purposes, they are divided into the following groups and sub-groups:

Group I. Lymphangioma simplex.

Group II. Lymphangioma cavernosum.

Group III. Hæmatolymphangioma (L. simplex et varicosum et cavernosum.)

Group IV. Lymphangioma (s. et v. et c.) with pachydermia.

The paper is continued.

Dr. T. Colcott Fox offers an interesting and unique case of

Keratosis of the Palms and Soles, Probably due to Arsenic.

The patient, a young man, aged 20 years, sought advice on account of a chronic intractable thickening of the skin of the palms and soles. Six years previously, shortly after his first and only connection with a woman, the patient suffered from multiple "sores" on the penis. At this time he did not consult a doctor, but fifteen months later, after a sea bath, he discovered a red eruption which developed into blebs. This eruption commenced on the chest, became generalized and continued off and on for some time. The bullæ formed crusts of considerable size and left faint scars. Syphilis appears to have been diagnosed by several well-known practitioners, and the term *rupia* was applied to the eruption. The patient states that he never had a sore throat or tongue, or bubos. He took iodide of potassium on one occasion only, but it "poisoned him." Mercury was administered in one form or another for four years and three-quarters, and arsenic for at least four years. Thus it is gathered from his prescriptions that the patient was ordered five minims of liquor arsenicalis thrice daily in October, 1888; fifteen minims of Donovan's solution thrice daily in November, 1888; about two and a half minims of liquor arsenici hydrochlorici thrice daily in February, 1889; then arsenious acid and liq. arsenici dydrochlorici for a time, and finally liq. arsenicalis in four minim doses, thrice daily, down to about September, 1892.

When the patient consulted the doctor in November, 1892, he informed him that the exhibition of green iodide of mercury pills just before a prolonged sea voyage, the discontinuance of other medicine, and the sea voyage itself, had greatly improved his health. All bullous eruptions had ceased

and have remained absent. He was still rather pale. His palms and soles were greatly thickened and disfigured, and in such a manner as to suggest an arsenical origin. His face had a peculiar but slight muddy tint, which might well have escaped notice. The neck was rough and dirty-looking, and his body much mottled with dirty-looking pigmentation, which was probably due to arsenic and not to pre-existing eruptions. The skin, generally, of the limbs and body was harsh and dry, with indications of faint desquamation, but without any psoriasiform patches on the elbows or elsewhere. There was an indication of a scar on the glans penis, but no other objective sign of syphilis, unless the condition of the palms and soles be considered such. The latter regions presented a considerabie thickening of the epidermis, simulating hereditary congenital keratosis.

The treatment consisted of local remedies only. The palms and soles thoroughly soaked in soda and hot water each day, and when the epithelium was sufficiently macerated, vigorously attacked with pumice stone. Then Unna's strong salicylic acid plasters were applied night and morning, and worn throughout the twenty-four hours at first. Under this treatment the condition rapidly ameliorated, and soon there were only isolated warts to deal with. When the patient was seen last the hands and feet looked quite cured and had wonderfully improved in his general health.

The causation of this palmar and plantar keratosis seems to have been either syphilitic or arsenical, though we must remember that the palms and soles assumes a somewhat similar condition under other influences such as in congenital pemphigus, and perhaps hyperidrosis. We are not in a position, however, as yet to estimate the influence of the arsenic frequently administered in such cases.

We know, however, that administration of arsenic, in certain persons, excites, amongst other effects, peripheral nerve and vascular lesions, evidenced particularly in the palms and soles.

NEWS AND MISCELLANY.

The International Congress of Charities, Correction and Philanthropy.

We invite the attention of our readers to the following circular, and would earnestly urge members of the profession to participate in the proposed congress:

One of the series of Internationl Congresses to be held in Chicago in 1893 is to be devoted to the subjects of Charities, Correction and Philanthropy, and the third section of this is to consider all matters relating to the hospital care of the sick, the training of nurses, dispensary work, and first aid to the injured. The Committee of Organization of the Congress has appointed Dr. John S. Billings, Surgeon U. S. Army, as Chairman of this Section, and Dr. Henry M. Hurd, Superintendent of the Johns Hopkins Hospital in Baltimore, as its Secretary, and has authorized and requsted them, to complete its organization, to extend invitations and to prepare a programme for its work. Miss Isabel A. Hampton, Superintendent of the Training School for Nurses of the Johns Hopkins Hospital, has been appointed chairman of that part of the work of the Section which relates to the training of nurses.

This Section will hold five sectional meetings of about two hours each, commencing June 12, 1893, and will also have charge of one of the general sessions of the Congress, viz: that held on the morning of June 14.

It is desired that this shall be a truly international gathering for conference on the subjects alloted to this Section, and all who are interested in hospitals, in training of nurses, in dispensaries, or in first aid to the injured, are cordially invited to be present, to contribute papers and to take part in the discussions.

The papers and proceedings will probably be printed as a separate volume, and it is hoped that this will represent the best methods and the best work in each of these departments in all parts of the world.

The following are suggested as subjects for special consideration in papers to be prepared:

1. Hospital organization—governing bodies—relations of the medical staff and of nurses' training schools.
2. Hospital finances—means of support—mode of accounts—cost.
3. Plan and construction of recently built general hospitals, embodying the latest improvements.
4. Relations of hospitals to increase of knowledge, to medical education, and to the medical profession. Hospital records, statistics and reports.
5. Pay patients in hospitals.
6. Isolating wards and hospitals for contagious diseases.
7. Hospital diets, dietaries, kitchens, etc.
8. Hospital ampitheatres and operating rooms.
9. Hospital laundries and disinfecting establishments.
10. Army and navy hospitals—emergency hospitals in time of epidemics—temporary and movable hospitals.
11. Small and special hospitals, cottage hospitals, school hospitals, private hospitals, sanitoriums, etc. Convalescent hospitals, and what to do with incurables.
12. History and present condition of hospitals in the large cities.
13. Training schools for nurses.
14. Dispensaries—relations to the public and to the medical profession. Dispensary records.
15. First aid to the injured. Associations for best means of popular instruction in and its place in general education.

Persons desiring to present papers, or to share in the discussions of this Section, are requested to communicate with the Secretary at once. The period of time alloted for the preparation of the programme is necessarily brief, and it is essential that all who are willing to assist in this work should act promptly.

Address all communications to DR. HENRY M. HURD, The Johns Hopkins Hospital, Baltimore, Md.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.
(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Sodc, one or two pills t aken three times a day.

Pil. Lady Webster.
(WM. R. WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.
(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.
(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

DEAR DOCTOR:

I have met you before and trust you remember me pleasantly. I am doing my best to prove worthy the confidence you impose in me. If you have a bad case of Rheumatism, Gout, Gravel, or any form of Uric Acid poisoning, send for me. I am not a cure all, but I know how to assist you in getting these poisons out of the system. I adopt the "American idea" so that I may not be mixed up with my foreign rivals. American products for Americans is the popular sentiment. If you wish to know who my friends are, send me word. I have a list of the most eminent physicians in the world who are always glad to say a kind word for me. If you doubt my ability to control disease, I will do my best to convince you without charge. My offices are:

SOME THOUGHTS ON GENERAL ANÆSTHESIA: TREATMENT OF ACCIDENTS OF ANÆSTHESIA.

WM. H. BURR, M. D., Wilmington, Del.

So much has recently been written on anæsthesia that it would hardly seem possible to furnish any new thoughts on the subject.

But each individual experience may develop something new, and we give the following for what it is worth:

In the first place, not enough is said about the manner of administration which, in our opinion, is one of the most important matters in connection with the whole subject.

We are not a very devout believer in the alleged phenomena of hypnotism, but think a mild form of that power is very important in preparing a patient for anæsthesia.

Perfect confidence, amounting almost to an assumed carelessness, should be shown by the operator toward the patient, and such control as it is possible to acquire should be had in that way. Some slight explanation of its effects may be made if it is thought necessary, but one of the most important things to be aimed at is to be able to control the patient by suggestion during the early part of the anæsthetic process.

That this is possible may be easily proved by anyone who undertakes to carry out the necessary steps, and without the patient being at all conscious subsequently of any attempt to control.

The different stages of the process at which this control is available are, 1st: The irritant stage, when the patient may cough, roll his head from side to side, strangle and make himself generally miserable. A little firm and reassuring address with careful regulation of the vapor will do much to tide him easily over this stage. 2nd: Comes that *dead point,* occurring in almost all cases of anæsthesia, and which to us seems the most frightful period in the whole process. It is the point reached just before the complete abolishment of sensation and movement, when the patient lying limp, seems to forget to breathe, meanwhile rolling his eyes and staring fearfully, and yet is intensely sensitive to outside impressions. At this time a few firm, imperative directions to "*breathe deeply,*" or, to use a more common expression, "*take a long deep breath*", with an accompanying friendly dig in the stomach will carry him easily, safely and comfortably into the third stage, or complete anæsthesia.

But there is another very important feature in this part of the process. Between this *dead point* and the beginning of the third stage lies the stage of excitation so much dreaded by all operators. It is here that control is all important, and the will of one weak man holding the inhaler is often just as potent and much safer than the strength of six lusty fellows to hold the unfortunate patient on the table. An excitable, ill-advised word or laugh, or a rude noise will often precipitate an explosion

that may require some management to conquer and may affect the whole subsequent process. On the other hand a firm word, reassuring but commanding, will obviate all the above unnecessary and unpleasant phenomena.

I have repeatedly seen the *dead point* spoken of above, which precedes complete anæsthesia, mistaken for complete anæsthesia by operators who ought to know better, and who, acting upon their mistaken idea, have plunged the scalpel into the sensitive flesh with the result of having the patient fling himself from the table in a paroxysm of excitement. It is very probable that very many of the cases of sudden death in the beginning of anæsthesia are caused in this way, by attempting to operate at this awfully dangerous *dead point*, before the third stage of complete anæsthesia. It is notable that women are much easier of influencing during anæsthesia and much less likely to go through the stage of paroxysmal excitement, and I think it is largely owing to the fact that they are more susceptible to the influence of man's will than is man.

In my experience, though I have had almost no cases of unpleasant excitement in women, I can say with one or two exceptions the same for men. The exceptions were men whom I had not the opportunity to see, talk with and impress with my individuality before beginning the process. In other words, they were already unconscious when I took the inhaler from the hand of an operator who did not believe in my system and did not undertake to practice it.

I am very glad to see that there is one person who agrees with me; vide: abstract from *Australian Medical Journal*, in THE MEDICAL AND SURGICAL REPORTER, Jan. 21st: "That the administration should be gradual and that the principal danger is in the beginning of anæsthesia" (and not after full development.)

Though it is held by many that each successive minute of anæsthesia increases the danger, I cannot altogether give credence to that idea and I often feel safer the second half than the first half hour of an hour's operation.

It seems as though the system in a manner adjusted itself to the condition of anæsthesia, and yet it would not be well to trust too implicitly to that adjustment, and the pulse and respiration must be watched with every sense that we possess, especially the patient's face. The operation should be as quickly done as is consistent with skill and precision. There is no doubt that a prolonged anæsthesia does depress the powers of life very much; and it should be constantly held in mind that in prolonged anæsthesia the transition from sensation to profound coma is often very rapid, requiring a very small quantity of the vapor to produce it. It is very common for operators upon the first returning sign of sensation, to urge, often imperatively and fretfully, the administrator to give the patient more ether, with the result sometimes, when the administrator is young or accustomed to defer, that he crowds on too large an amount and the result is unavoidable (?) death from ether; cause, some idosyncracy of the patient. Real cause; some idiosyncracy of the operator.

The man who gives an anæsthetic ought to have a thorough and complete understanding of the whole subject of anæsthesia, and then he ought to pay very little attention to the directions of the operator except to reassure him from time to time as to the condition of the patient, and to do a little polite lying, if necessary, when requested by the operator to give more than he thinks advisable. The operator is in a position to know little or nothing of the physical condition of the patient, and he ought not to have the added responsibility and anxiety to bear. The commonly accepted signs of complete or incomplete anæsthesia are very unreliable, as anyone will find who attempts to go by them. The sensitiveness of the cornea for instance, is one of the most unreliable. I have seen a person whose cornea was extremely sensitive as proved by movement in the muscles of the lid, yet who was on the verge of deadly coma. Even extensive muscular movements of the legs and arms, with movements of the body and efforts to articulate words, are often present at the same time the patient has all of the anæsthetic that he ought to have.

It is not always safe to push it in those cases of excitement, but often with a careful continuence of the process and perfect quiet the excitement will subside, and the organism will adjust itself to the conditions of anæsthesia when it will be sur-

prising how little vapor will be found necessary. If death occur in the later stages of anæsthesia there would seem to be less excuse for it than in the early stages, especially if it come on gradually as in chronic disease processes.

We have never been so unfortunate as to be present when complete death resulted, but have been there when we think it would have taken an astute and learned professor to say that the patient was not dead.

It was a colored woman in labor some several days. A professional sister was using Barnes' dilators and I was using chloroform. The patient was very hard to influence and much chloroform was used. Being somewhat of a green hand, I was foolishly depending on that greatest of all fallacies the *sensitive conjunctiva.*

The patient was stertorously breathing, when she stopped and, as near as I could make out, she had not any pulse either. She was limp as a rag. I jumped on the bed and caught her by the heels, took one on each shoulder and throwing her over my back, stood up as straight as I could on the bed. Two slats came out and I took a fresh hold. I called for a bit of rope and tied the two heels together over my neck until some of the men folks could arrive and help me. I weighed about 130 pounds, was weak as a cat and consumptive; the woman weighed about a ton. In the mean time my professional sister with a wonderful control of mind and heart, was slap-dashing cold water, wet towels over the chest; pulling out the tongue and attempting to use artificial respiration, and at the same time keeping my heart up, for which I shall bless her to my dying day.

The patient gave a gasp after what seemed an unconscionably long time; presently another, then another and shortly began a sort of apology for breathing. Did I lay her down? Not I. Mindful of Tait's experience, I held her there listening to the welcome breath sounds for so long a time it seemed to me an half hour. When we finally laid her down the position of fœtus had entirely changed; the os, which had resisted dilatation for days, was widely open and labor went on most comfortably being completed in a few pains. A dead child being the natural (?) result.

TREATMENT OF THE ACCIDENTS OF ANÆSTHESIA.

In the treatment of the accidents of anæsthesia there seems to be very little accord or general agreement. It is a reproach to medicine and very unfortunate that such should be the case in the treatment of any condition, much more the grave complications which we sometimes meet with here.

Is it not enough that our friend the homeopath should be satisfied with superficial and hypothetical analyses of diseased conditions, and still more superficial and absurd therapeutical applications to those conditions. We ought to have a thorough and rational idea of any pathological condition that may arise and then apply remedies in an equally rational manner.

What then is the condition likely to arise which will require active treatment, and what treatment is the best and most likely to be fruitful of good results? The condition most likely to arise is overcrowding of ether which probably acts in two ways; first by its narcotic or poisonous effect on nervous matter composing the important centers of respiration and circulation; second by its mere presence mechanically preventing access of sufficient oxygen to those centers.

The treatment then, of course, will be to supply air to the blood.

Open the windows and invert the patient—generally the last things that are thought of. People cannot get it out of their heads that anæsthetics are not chemical poisons in the true sense of the word, and the most that is necessary is to supply fresh oxygen, and allow the system to eliminate the agent. Inversion and fresh air is the treatment of all cases where the patient has apparently ceased to breathe. There should be no time wasted in endeavoring to perceive whether the heart is acting or not. Prompt inversion, not allowing an instant to intervene, for in one instant who knows but that the patient may cease to live.

Throw the patient over your back, taking him or her by the heels and allowing the head to hang as low as is possible. Time, place or propriety have nothing to do with it. It is a case not of life or death, but death or life, with death in the preponderance.

The rationale of this is perfectly intel-

ligible. It is that you shall produce by means of gravity that which you cannot by means of the vital pump. Because the vital pump is for the instant collapsed, no good, struck for higher wages. By means of gravity you bathe the paralyzed nerve centers with what amount of oxygen there is left in the vitiated blood current, and thus in many cases start up the whole apparatus of circulation and respiration.

And this brings us to the second part of our treatment and that is artificial respiration. How, let me ask, will it be possible to practice any of the various methods of artificial respiration, whether it be Marshall Halls' or the Sylvesterian or what not, in the inverted position?

You must either sacrifice the position, which I am afraid is too often done, or find some new method of introducing air into the lungs.

And a method that commends itself to me is one that I saw mentioned not long since in the REPORTER, *i. e.*, direct insufflation mouth to mouth. I have never had occasion to try this in an adult, but have used it in several cases of comatose babes, which might have been in another world if I had not hoped, believed, and been patient. Some of these babes were white and some were black, some came by the breech, and some had the cord wrapped tightly around the neck. All were blue, limp and apparently dead. I do not remember ever to have failed to resuscitate any of them, and my method has always been the same. A large bowl filled with pretty hot water, some of which is dipped out from time to time and hot water introduced in its place. The babe is *suspended in your hands in the hot water from which it is raised for an instant from time to time, and the end of a towel wet in cold water dashed against it's back and chest. Direct insufflation into the lungs mouth to mouth. I have kept this up for three hours, the perspiration rolling off me and my bones feeling as though they had been through a rock breaker. And finally had the satisfaction of seeing the limp and apparently lifeless, cold and blue body become warm and red. Then wrapping the babe in raw cotton I toast it before the fire, and in a few hours it is dressed. It does not need washing.

*Horizontally. In my experience inversion does not seem to be very beneficial, especially if kept up very many seconds. Occasional inversion for a few seconds has seemed useful

I don't mean to say that the babe *is* dead. Often I have fancied that I could hear a feeble heart beat though I don't spend very much time making a critical examination.

But it does not breathe, and in all probability would I think be classed as dead birth if its blue and cold body had not been warmed into life at the same time that the breath of life was blown into it to perpetuate that warmth and life. In the beginning of my career I used to use a tube, especially if it was a black babe, but very soon threw it aside. There is no time to think of nice points such as possible infections, blood poisoning, etc. A life is at stake, a human life, and if a man saves one life in his own lifetime he may have accomplished something.

The theory of the hot water is this:—in the first place it makes the best medium possible for imparting an equalized and regular temperature to the child's body, and has the advantage that it can be nicely regulated by the addition of more hot water by displacement. Besides which I am of the opinion that with each moment that the blood is allowed to remain cold at the surface of the body, is the hope lessened that it shall be made to move and circulate healthily in the vessels.

* * *

Of course if the patient has a hemorrhage in any part of the brain, all the artificial respiration and stimulation in the world probably are not going to help him.

But the question is, might not that hemorrhage have been avoided if the conditions of circulation had been watched?

For instance there is in many cases of anæsthesia, especially in the early stages, an irregularity between the action of the heart and lungs respectively. The heart replying to the stimulant action of the ether may be acting vigorously while the respiratory center is obtunded and the patient in a manner forgets to breathe.

The refusal of the lungs to take the blood from the heart, coupled with the obstruction which the circulation has to overcome from the fact of a normal amount of oxygen being absent, would still more cripple the heart and, if the patient had any weakness of the coat of any blood vessel, it would give way to the active pumping.

A summary of the general advice

given for the treatment of the accidents of anæsthesia wonld read about as follows: If there are symptoms of failure of respiration or circulation, lower the patient's head; allow ingress of fresh air; give hypodermically whiskey, ether, digitalis, strychnine—any or all of them.

If the patient has ceased to breathe use some method of artificial respiration. And incidentally it is advised to use a medium strong Farradic current. This brings us to the last point in our treatment. The use of drugs—And here there is no general agreement, but one thing may be doubted, one would think, and that is that when the circulation is in a very weak condition there will not be very rapid absorbtion.

THE DIFFERENT FORMS OF IRITIS AND THEIR TREATMENT.

ARTHUR D. MANSFIELD, M. D., Baltimore, Md.*

Iritis, so disastrous in its effects upon the eye, is perhaps the one disease that may be the most easily mistaken for a simple inflammation and yet when recognized it will yield most beautifully to proper treatment.

I submit that iritis exists in three distinct forms. 1. Simple iritis; 2. Plastic iritis; 3. Suppurative iritis.

Under the second form I will include *a.* Syphilitic iritis; *b.* Rheumatic iritis; *c.* Traumatic iritis.

These latter forms may easily, and sometimes do, pass into the suppurative form —especially the syphilitic iritis.

SIMPLE IRITIS

is an affection of the iris in which inflammation exists in the simple form, and in which we have the vision impaired to a more or less extent. Objects that are easily discernable by the eye in its normal condition can hardly be seen, or seen as if a mist had completely enveloped the object. The eyelids are closed that all the light may be excluded. Photophobia exists to a marked extent, dependent entirely upon the intensity of the inflammation. The cornea as a general rule is not cloudy in simple iritis, though in the graver forms it may be clouded and even opaque.

One very noticeable and diagnostic feature of iritis is the circum-corneal injection which is very characteristic, once seen can never be mistaken and is very often of considerable assistance in making the diagnosis. This circum-corneal area of injected blood vessels presents a uniform pinkish appearance, not red in any one part more than in another, and appearing rather deeper than the conjunctiva, which in reality is the case, the vessels injected being scleral vessels. The injection of these vessels is pathognomonic of iritis. Pain may exist in simple iritis, (not the painful vision which we know as photophobia, but characteristic temporal and frontal pains,) or may be absent entirely. There is no more variable or inconstant symptom of iritis than pain.

The iris itself presents the most characteristic changes. The iris is sluggish, slow in moving when light is thrown upon it by the focal illumination obliquely, not because it is attached to any substance that holds it in its place, but because the exudation from the inflammatory area prevents the proper functioning of the muscle fibres. The iris also changes its color very materially, taking on an ugly yellowish brown. It has the appearance of being elevated by small excrescences, in the shape of small papules or cilia and gives one the idea of fungoid growth. The color of the healthy iris has much to do with the color of the inflamed iris, the mixture of the two colors rarely resulting in a pleasant combination. The amount of color change may be very small indeed, in fact may escape a casual observation and require a very close examination. The change usually begins at the pupillary orifice and gradually extends toward the periphery in lines gradually merging, thus forming one complete surface of muddy, inflamed area.

The treatment of iritis differing somewhat in degree according to the intensity and variety of the inflammation, is

* Assistant Surgeon at the Presbyterian Eye Ear and Throat Charity Hospital Baltimore, Md.

pretty much the same, consequently I will omit to speak of that now.

PLASTIC IRITIS.

The symptoms of this form of iritis differ in degree of intensity from the former. We have pain in the frontal and temporal region, in fact in every part of the head and even down the back, but the pain is particularly marked in the frontal and temporal regions. Photophobia exists, the vision is impaired greatly, the aqueous humour is cloudy and murky, the membrane of Descemet is inflamed and swollen, sometimes the cornea also, the substance of which may be infiltrated and the transparency of which is consequently impaired. The iris is muddy, sluggish, and the pupil may be dilated or contracted, may be bound to the lens by plastic adhesions in its entirety, or only in separate points, thus giving it an irregular appearance. The circum-pupillary area is always changed in color more than any of the other parts, this area seemingly being the most susceptible of all the parts of the iris to inflammation; there may be part of the pupil occluded or there may be an entire occlusion with the iris bound to the lens in every part and a plastic membrane thrown over the pupil. Or this plastic membrane may not be present and the pupil free so far as admission of light is concerned, yet, the communication between the two chambers, prevented. This in itself is a matter of serious consequence as the anterior chamber depends upon the ciliary bodies behind the iris for its supply of aqueous humour; such a condition is known as total posterior synechia or occlusion of the pupil.

The first subdivision of this form is syphilitic iritis. In this we have the form of iritis capable of the greatest destruction and damage to the eye, and yet, in an otherwise healthy and vigorous constitution, it is most tractable and yields most readily to treatment. It is on this account that syphilitic iritis is the most preferable form to treat, because syphilis is so amenable to the use of iodide of potassium. Syphilitic iritis comes on as a secondary symptom of syphilis and may be accompanied by a rash general in character. Pain is rarely very great, certainly not in proportion to the inflammatory condition of the eye. Gummatous nodules make their appearance very often during the course of syphilitic iritis. I have noticed these gummata to appear more frequently in the negro than in the white; this may have been a coincidence of hospital practice and have no value whatever. Sometimes these gummatous growths suppurate and fill the anterior chamber with pus.

These gummata often leave a cicatrix causing a permanent change or alteration in the iritic substance.

The next subdivision of plastic iritis is that very stubborn, very slow form known as rheumatic iritis, seen in patients that have had rheumatism for a longer or shorter time—usually in old persons that have become completely saturated with rheumatic poison. Such iritis means slow recovery, for the reason that rheumatism yields slowly to general treatment, and this shows the vital difference between syphilitic and rheumatic iritis.

Rheumatic iritis is attended with severe pains in the head, and in the eye the conjunctiva is very much injected and swollen; at times the scleral vessels are congested and the sclerotic being a fibrous structure takes on the specific rheumatic inflammation. While the pain is greater and the injection and apparent inflammation greater in rheumatic iritis than in syphilitic, the exudate is less and consequently the damaging results and sequelæ from exudation are less liable to occur, as we rarely see such damage wrought by rheumatic iritis as by the syphilitic form.

Syphilitic iritis has a greater tendency to cause adhesions than has rheumatic iritis, is shorter in duration, and when alleviated speedily recovers and has no tendency to the relapses which are so numerous in rheumatic iritis. Again the color of the iris is not changed so much in rheumatic iritis as it is in the syphilitic form, simply because we do not have that immense amount of exudate in the former.

The third form of plastic iritis is that seen following a traumatism of any kind, whether penetration of the globe is accomplished or not. In many cases a blow is received in the eye and a violent inflammation ensues. The conjunctiva becomes reddened, swollen and œdematous; the iris congested and changed in color; the pupil sluggish in response to light, and all the phenomena of iritic ad-

hesions may form if the pupil be not properly dilated. The blow may have caused a wound of the cornea, perhaps not sufficient to allow of hernia of the iris, yet sufficient to allow the escape of the aqueous humour and the formation of anterior synechia—the iris becoming adherent to the cornea. The part which usually becomes attached to the cornea is the pupillary margin, the pupil is usually elongated and drawn toward the wound in the cornea, the usefulness of the eye being impaired.

SUPPURATIVE IRITIS

Usually follows a gumma—though it is not always a result of syphilis. The gravest affection of the iris is this suppuration because such destructive changes occur.

Rapid are the changes in this form of inflammation. The color of iris becomes quickly changed, the aqueous and cornea become cloudy and murky, the eye intensely inflammed with much pain and photophobia, the iris is perceptibly swollen and bulged forward, the pupil very sluggish and oftentimes immovable and entirely closed with no reflex whatever to the ophthalmoscope .

There usually appears a point of inflammation and suppuration in the substance of the iris, which sooner or later discharges a purulent substance, which graviates to the bottom of the anterior chamber and may be so great as to reach the level of the pupillary orifice.

Suppurative iritis is usually associated with a lowered condition of the system. Suppuration may also result from a traumatism. The suppuration is not at all limited to the iris, but may extend throughout the uveal tract to contiguous areas. The vitreous may become muddy, and the result may be panophthalmitis.

In the treatment of iritis one point takes precedence over all others, it is to always *dilate the pupil.* The reason for this dilatation is to keep the edges of the iris from the margin of the lens, and to facilitate emptying the globe of deleterious matters by a free circulation through its vessels and canals.

The best means of preventing these adhesions is the use of atropine. A weak solution may be used at first if no adhesions have formed, and the dangers are averted. A one per cent. solution of atropiasulphas in water, instilled every two hours in the initial stage of iritis, no matter of what variety, will prevent adhesions. Should the adhesions have formed, we must use stronger solutions until we have broken them. The use of an ointment consisting of vaseline one drachm, atrophia sulphas five grains, every hour for a few hours, and then every two or three hours, will prove very efficacious in breaking adhesions that have resisted weaker solutions. The iris will dilate where it is unattached, thus giving an irregular shaped pupil showing the point or points of adhesions. It has been recommended to use alternately, solutions of atropia and eserine. I cannot commend this method as I think it inflicts unnecessary pain without accomplishing any benefit, certainly not sufficient to justify its use. The atropia being a more powerful drug than the eserine, the latter has no appreciable effect whatever.

Atrophia is our most valued drug in the treatment of iritis and yet occasionally we must dispense with its use because it causes too much local irritation, and also causes constitutional changes peculiar to belladonna poisoning. Occasionally a single installation of a solution of atropia will cause all the violent symptoms of atropism. In such cases we are not at a loss for a substitute, as we have hyoscyamine, duboisine, hornatrophine, with their salts. The duboisine should be used in weak solutions as it is possible that idiosyncrasy may exist for it as for the other mydratics.

The relief of pain and of congestion seems to be next in importance. Atropine is a sedative and tends to alleviate the pain; heat in general will diminish pain; a good way is to immerse the eye in a cup full of hot water and then apply dry hot cloths or cotton wool. The use of leeches, natural or the artificial often relieves pain by depletion. The amount withdrawn by the leech should be about an ounce. Salicylate of soda, 10 to 15 grains every three hours, will sometimes relieve the pain considerably. A *dernier resort* for relief is paracentesis of the anterior chamber; this, when properly done, rarely causes any unpleasant effects. The wound in the cornea should be prevented healing by the insertion of a blunt probe,

that the tension may be relieved as much as possible.

When iritis is seen in its early stage, iced applications are far better than warm or hot applications. The latter rather tend to promote inflammation, while in the early stages cold tends to abort it. In cases that assume a chronic appearance —better one week and worse the next—the most reliable remedy is iridectomy, which should be done upwards when the tension of the eye becomes plus and the other symptoms marked showing no signs of disappearance. Each case should be judged on its own merits and no hard and fast line can be laid down.

If a few points of adhesion exist and no recurring attacks appear, it is far better to let the eye and the adhesions alone. But should iritis appear from time to time it is necessary to free the iris from the lens.

One method is to make the corneal wound as near the attachment as possible and large enough to admit the introduction of the forceps, and seizing hold the iris draw it away from the lens, thus liberating it, being careful, of course, not to wound the lens. Another method is to make the corneal incision opposite to the attachment, then passing a hooked spatula in and beneath the iris, try to lift it from the lens. After each of these operations use atropia and close the eye with a light bandage. In cases where we have total occlusion of the pupil, with total posterior synechia and no communication between the anterior and posterior chambers, the best method is free iridectomy upwards and downwards; this method has a two-fold value, establishing communication between the two chambers and, at the same time, forming an artificial pupil which enables the eye to discern objects.

In iritis with suppuration and hypopyon, paracentesis is the only means to be employed. In some cases, when the amount of pus in the anterior chamber is small, the use of constitutional remedies often absorbs the exudate. Blood-letting is contra-indicated in all such cases, as are all remedies that tend to lower the vitality. Of course, systemic treatment is indicated chiefly in syphilitic and in rheumatic iritis. For the relief from pain we may resort to chloral hydrate or morphia, either internally or hypodermically.

When syphilis is undoubtedly present we should push mercury and iodide to the full limit. If necessary mercurial inunction should be practiced, and kept up until signs of the disease begin to disappear. My usual method is to give ¼ grain proto-iodide of mercury in an excess of iodide of potassium, and increasing the dose until the disease shows signs of abating. In rheumatic iritis the treatment, as a general rule, will not be so encouraging as in the former. Rheumatic iritis, in my experience, has been very tardy and frequent relapses occur, simply because the iritis appears very late in chronic rheumatism, while iritis appears as a secondary symptom of syphilis and manifests itself early in the disease if it is going to appear at all. With salicylate of soda and the general alkaline treatment I have found as good results as with any other.

Dandruff Cures.

A correspondent of the *Lancet* asked for advice regarding very persistent dandruff which affected a female patient, and he has received the following responses:—Dr. David Couper, of Glasgow, advises the patient to wash well the roots of the hair twice daily with a lotion composed of perchloride of mercury in a saturated alcoholic solution of boracic acid (quantity not stated). When this has dried let her rub in an ointment of sulphur and carbolic acid—say, 20 grains of the first and ½ drachm of the other to the ounce—using lanoline or lard, or a mixture of both as an excipient. Dr. E. Curtin says he has had good results in obstinate cases of scurf of the scalp by washing the head in warm water containing about 3 drachms each of sod. bicarb. and liq. picis carb. to the quart, and afterwards applying ichthyol ointment. Dr. E. Fenoulhet, of Herne Bay, suggests a weak sulphur ointment. He has used it of the strength of 2 drachms to the ounce of vaseline in a most obstinate case of dandruff with complete success.—*Ex.*

Coffee as a Cause of Itching.

Dr. Brown Sequaid again draws attention to the fact that occasional Pruitus Ani depends upon drinking coffee, and publishes a case in which leaving off the beverage completely cured a case, the malady returning on recommencing the beverage. —*Therap. Monat.*

CLINICAL LECTURES.

LYMPHADENOMA.

E. FLETCHER INGALS, A. M., M. D., CHICAGO,*

This young man is 23 years of age. He comes to us from Iowa, complaining of a cough which has lasted for about two months. He is a farmer, and so far as we are able to learn, has lived a regular life. He claims that he has had no venereal disease and there is no reason to suspect it. You notice that the face, ears and nose are congested, and this is especially marked when he has been out in the cold. He tells me that about five months ago he first noticed some swelling in the neck, on the right side, just above the clavicle. About two months afterwards he noticed also a little swelling upon the left side. Three months after he first noticed the swelling upon the right side he began to cough, and he has now a short, hacking, sometimes paroxysmal, cough which is very troublesome. He had very little pain and did not at first consider the cough a very annoying symptom. The sputum is comparatively small in amount. He has been troubled with shortness of breath since the cough began. During the last two months the symptoms have steadily increased and he has been unable to work for five weeks. On the 10th of December he had a strangling spell with the cough, lasting several minutes, during which he thought he was dying. The difficulty in breathing has gradually increased until he now gets out of breath in walking an ordinary block. During the last few weeks his appetite has been poor and he thinks he has lost considerable flesh. I find that he was subject to frequent attacks of croup until he was 12 years of age.

Inquiring into the hereditary history we find nothing whatever. His father who came with him appeared to be a sound man and told me that on neither side of the family has there been any hereditary disease that he knows of.

I find the temperature 100°; pulse 100 and about three-fourths as strong on the right side as on the left. The voice is slightly hoarse, but there are no other symptoms.

Examination of the nasal cavities shows that the right side is about three-fourths closed by swelling, but this is probably due to an acute cold. The uvula and pharynx are slightly congested, (about ten per cent). The tonsils are normal.

On examination of the larynx I find only about five per cent. of congestion and the cords move freely; the arytenoids overlap each other fully one-fourth during phonation, although such a condition is frequently found in health and both sides move alike in this case, I see no reason to think that this change in the movement of the arytenoids is in any way due to the disease. I am unable to see the trachea except in the upper part which I find congested about five per cent. As a standard of congestion 100 per cent. would indicate the deepest red which might result from catarrhal inflammation.

Upon superficial examination of the neck we observe on the right side just above the clavicle, a movable swelling, somewhat nodular and appearing to be made up of a number of glands. It is about two inches in its lateral diameter, about two and a half inches vertically and apparently about an inch in thickness. Upon the left side we find a similar enlargement just above the outer portion of the clavicle, an inch and a half in its different diameters and not more than three-fourths of an inch in thickness. On the right side there is a slightly enlarged gland a little below and back of the inferior angle of the jaw. There are no enlarged glands on the posterior aspect of the neck. There is a slight enlargement of one of the axillary glands, but not more than might be found in many healthy persons.

You will observe the prominence of the superficial veins which are quite tortuous and stand out distinctly over the upper portion of the chest, more especially upon the right side, running over the right shoulder and down the right arm. You see also a diffuse swelling at the anterior

*Professor of Laryngology and of the Practice of Medicine in Rush Medical College.

and lower portion of the neck, extending from side to side, not quite as prominent upon the left side as it is upon the right. The swelling is soft and elastic with no enlarged glands beneath it. It is due to turgescence of the smaller veins caused by obstruction to the return of blood to the heart as indicated by the enlarged and tortuous veins.

The movements of the chest are not as free as in most healthy men, but they are alike on both sides. The respiratory movements are much more pronounced at the lower part of the chest than at the upper. I find an abnormal area of flatness at the upper part of the sternum as low as the third rib, extending into the right and left intra-clavicular regions. By careful percussion I find that it extends about an inch to the right of the sternum and from the third rib to the clavicle. There is also very decided dullness about an inch in width extending along under the right clavicle an inch farther toward the shoulder. As I percuss to the left of the sternum, I find an area of flatness extending from the third rib to the clavicle, the outer border of which runs upward about half an inch from the sternum in the second interspace. Over the whole area of the upper portion of the sternum down as low as the third rib (right), we have perfect flatness extending under the right clavicle and to the middle third of the left clavicle. The resonance at the inner portion of the suprascapular region is not quite as great as normal, but still there is not a distinct flatness. I find the apex of the heart in the usual position and the sounds normal. There are no abnormal murmurs heard over the upper part of the heart.

Upon listening over the lungs, I find distinct respiratory sounds over every portion of the lung except in the small area where we get the flatness. I find, however, that there is a loud, tubular sound, not very pronounced but still distinct, differing from that which we get in a healthy chest. This we might call a sonorous rale and as the sound is heard all over both lungs it must come from the trachea. If it were from a bronchus it would be heard on one side only. I find on the right side of the sternum a little of the bronchial element in the murmur, sufficient to distinguish it as broncho-vesicular. Distinctly over the sternum I hear nothing whatever of the pulmonary sounds, either bronchial or otherwise. A little to the left I hear broncho-vesicular sounds, but not as distinct as upon the right side.

The symptoms and signs in this case are evidently caused by a growth back of the upper part of the sternum, which is probably connected with the tumor visible above the clavicle.

A tumor occurring behind the upper part of the sternum has about nine chances out of ten of being an aneurysm. As a rule aneurysms do not occur in patients under 45 years of age; indeed they are quite exceptional in young patients. Aneurysms are apt to cause difference in the radial pulse of the two sides such as we find here. An aneurysm may cause a murmur, but not necessarily. I think in fully one-half of the cases I have seen of aneurisms of the aorta, there have been no abnormal murmurs. An aneurysm is also apt to cause more or less enlargement of the veins of the surface by obstructing the return blood through the descending vena cava or through one of the innominate veins. Aneurysm of the aorta is almost always attended by a peculiar pain, which is apt to be present in the very beginning, possibly before the patient experiences any other discomfort. This patient has had no pain in the upper part of the chest. In cases of aneurysm you will nearly always be able to feel pulsations, by pressure with the hands upon the anterior and posterior surfaces at the point where the tumor lies, even though the pulsations may not appear upon inspection or by palpitation on the surface only. We get no pulsation whatever in this case. Although in this case there are some symptoms and signs similar to those of an aneurysm, the patient's age, the absence of pain and of pulsation over every part of the tumor, the existence of a tumor above the clavicles and the absence of abnormal murmurs are ample to enable us to exclude aneurysm.

An abscess of the mediastinum would seldom be attended by enlarged glands above the clavicle; it would usually cause pain and would nearly always be attended by hectic fever and marked constitutional disturbance. This patient's general condition is excellent; there have been no rigors, and little, if any, fever and there is no pain; we can, therefore, exclude abscess with safety.

Somewhat similar symptoms to those we have found here may result from thickening, the result of syphilis; but we have no evidence of syphilis in this case, and as the boy has come from the farm and appears truthful in his statements, and there are no ear marks of the disease, we ought not to accuse him of having had it.

Nearly all solid growths in the mediastinum are malignant, though they are not necessarily true cancers. We have, for example, in the affection known as lymphadenoma a disease which, although not cancer, has in this locality a malignant clinical history, and I know of no possible way whereby we may accurately differentiate between it and true cancer. In this case the following features point to the diagnosis of lymphadenoma; there are several enlarged glands above the clavicles; the patient manifests no peculiar cachexia and he has no pain. In true cancer there is usually pain, and cachexia is commonly developed comparatively early. Lymphadenoma is apt to crowd the lungs before it; cancer to involve every tissue with which it comes in contact. The lungs in this case seem to have been crowded before the tumor to the right and left of the sternum. If we had here true bronchial breathing we would conclude that the lungs were involved, either by infiltration with cancerous deposit or by inflammation caused by pressure; but the sounds which we hear in this case are so feeble that they may be transmitted from the trachea. We cannot say positively t the lung tissue itself is or is not involved; but as the patient has no expectoration the chances are that the lung is simply crowded before the tumor and that the broncho-vesicular sounds are transmitted from the trachea and larger bronchial tubes.

The diagnosis is thus narrowed down to either lymphadenoma or carcinoma, with the weight of evidence in favor of the former.

Practically all cases of mediastinal tumor of any size are malignant. I may say, with reference to the prognosis in this case, that it makes very little difference to the patient whether we call it lymphadenoma or carcinoma; the progress of the case most assuredly will be from bad to worse. The chances are that this tumor will continue enlarging, pressing more and more upon the trachea or bronchi until breathing becomes difficult or deglutition is prevented. By compression of the trachae and the lodgment of tenacious mucous at the point most constricted sudden death may be caused, or, as frequently happens in these cases, the disease may cause inflammation of the lung with abscess or gangrene. If the tumor presses on the œsophagus he may die from starvation.

As to the treatment, unfortunately there is nothing which seems to hold out any hope for this patient. There can be no hope from the surgeon's knife. We will put him upon the iodide of potassium and chloride of calcium to see whether any reduction of the glands can be effected by these drugs. I have on previous occasions told you that in simple enlargement of glands chloride of calcium sometimes has a pronounced effect, and iodide of potassium acts similarly. Another reason for prescribing iodide of potassium is, that sometimes even malignant growths will, for a time, diminish under its influence. We will give this patient 7½ grains of each of these remedies, and gradually increase the dose to fifteen or twenty grains of each. I shall have him weighed daily in order to ascertain the effects of the drug. If it acts favorably we will expect an increase in weight. If, on the contrary, it has no beneficial influence, then we will expect the patient's weight to gradually decrease. If the weight augments the remedies will be continued, but if at the end of ten days he has lost two or three pounds, we will send him home with whatever comfort we can give him, feeling sure, however, that his prospects for recovery are gloomy.

I am especially glad to show you this case as it is one of extreme and unusual interest, and while it is true that no clinician can frequently present such cases on account of their rarity, still you may happen to fall upon one in your practice, and you will be aided in making a correct diagnosis after having seen this one.

To prevent or to put a stop to the formation of new tissue in the kidneys, in cases of interstitial nephritis, Prof. Da Costa believes that the bichloride of mercury is of more value than the iodide of potassium.—*Ex.*

COMMUNICATIONS.

AN UNUSUAL CAUSE OF RETAINED PLACENTA WITH CASE.*

J. H. VAN EMAN, M. D.†

Mrs.—, æt twenty-three; married at nineteen; the mother of three children, the last born Sept. 22d, 1892; has always been healthy, though subject to intense headaches, particularly since her marriage. She is a good sized, healthy looking young woman. Her first child was born about a year after her marriage, was alive, and the labor, though somewhat tedious, terminated with the unaided powers of nature and without a torn perineum. The second child was born less than two years after the first, and this labor resulted in a badly lacerated perineum, which was properly repaired with a good result. She did not menstruate after her second labor, and did not know she was again pregnant until her increasing size and later, the fœtal movement, gave absolute evidence as to her true condition. Her third pregnancy was uneventful excepting an almost continuous pain in the right side near the level of the crest of the ilium.

She was taken in labor Sept. 22d, 1892, and was in labor for about twelve hours. The first stage was slow on account of the early escape of the amniotic fluid. The second stage was rapid. The child large and plump. The cord a good length and not around the child's neck. An examination made immediately after the birth of the child showed a large and very firmly contracted uterus. Making further investigation twenty minutes later, I found the placenta was entirely within the uterus, only the cord hanging out of a firmly contracted os. No attempt having been made by the uterus to expel the placenta at the end of forty minutes, the vagina was well cleaned out. Introducing my fingers into the vagnia and thence into the cervix, I found the entire placenta firmly adherent to the right antero-lateral uterine wall. Passing my whole left hand into the vagina and steadying the uterus with the right hand, by working slowly and carefully, I separated the placenta from the uterus. I was compelled to introduce my whole hand into the uterus and found not only universal adhesion to the uterine wall, but also that it extended outward to the right into a funnel-shaped opening, which on manual examination proved to be the right Fallopian tube. The adhesions once thoroughly broken up, the uterus promptly contracted. The placenta and my hand were expelled from it at the same moment. After being thoroughly cleaned up the patient became quite comfortable. Her convalescence, barring her intense headaches, was uneventful, no rise of temperature occurring at any time. The lochia was moderate in quantity and without any odor. At the end of a week she was dismissed as being entirely out of danger.

This case is reported not for the purpose of making an argument for early interference in cases of retained placenta, but as a text for opening up and bringing on a discussion on a subject generally considered as settled by physiologists and obstetricians; viz: where does the ovum in the human female become fecundated?

The process of procreation may be divided into at least three steps:

1st. Ovulation.
2nd. Fecundation.
3rd. Fixation of the fertilized ovum.

According to Leopold and other authorities ovulation, consists in the rupture of a matured Graafian vesicle, which event usually takes place during a menstrual period, but may occur at any time, as in my case and many others on record. Impregnation having occurred without any evidence at all of menstruation.

At the instant of rupture of the vesicle one of two things must occur, either the fimbriated extremity of the Fallopian tube grasps the ovary, and the egg drops into its trumpet-shaped end, or the ovum is carried into the mouth of the tube by a ciliary movement of the epithelium. Once in the tube it is more or less rapidly carried through it to the uterus by the ciliary movement of the epithelium of the tubular mucous mem-

*Read before the Western Association of Obstetrics and Gynecology.

†Professor of the Diseases of Women Kansas City Medical College.

brane. In the rabbit it is said to do so in seventy hours; in the dog in eight days. In the human female the time is unknown. According to the books, after copulation the spermatozoa swarm around the ovum, each one endeavoring to effect an entrance into it. After a time the stronger and more active of the crowd effects an entrance into the ovum, its tail disappears, its head forms the male proneucleous and uniting with the female proneucleous, the act of fecundation is completed. The balance of the spermatozoa lay superfluous on the stage and soon retire from the scene. This is the earliest act in the creative plan, of the survival of the fittest. Everything is now ready for the third stage. The fertilized ovum following some unknown law, or possibly no law at all, either passes down the tube into the uterus where, usually high up on the posterio-lateral wall, sometimes low down, even to or below the internal os, fixation finally occurs. The decidua rapidly rises around it and soon encloses the embryo in a dome-like covering. From this time, the conditions and position being favorable, the development of the fœtus goes on to full term. This as I understand it is the teaching of the physiologists and obstetricians of to-day.

To the first postulate I agree; from the second I dissent. I deny that in man fecundation takes place in the tube. Excepting in those cases where, as a result of disease, the cilia of the tubes have been destroyed over a portion of their length, thus making a break in the highway along which the ovum is carried. The ova, being absolutely passive, remain at rest on being carried to the broken bridge. The spermatozoa, having an independent movement of their own, are able to cross over the damaged portion of the tube, fecundation occurs, fixation takes place, and as a result we have an extra-uterine pregnancy. Normally fertilization takes place in the uterus only, fixation occurring at the same moment and that point becomes later the center of the placental attachment. Should the contact of the two elements occur late when the ovum has descended low in the uterus, to the internal os, or possibly even below that point, we have as a necessary result, placenta previa. This theory or one very similar was, so far as I have knowledge first enunciated by Lowenthal years ago, later I believe by Tait. Permit me to further crave your patience while I give a few reasons for my belief.

1st. All investigations in this direction have been made on the lower animals. Their laws of procreation differ widely from those of man. The female permits the approach of the male only at such times and at such a season as is most favorable to reproduction. Impregnation being accomplished the rut or heat of the female ends at once and promptly. Should fertilization not take place, no sexual desire is manifested until, in the cycle of ovarian changes, impregnation again becomes possible. It is hardly necessary for me to say that in the human animal a somewhat different law seems to govern. It has already been stated that in the dog it has been demonstrated that it requires a period of eight days for the ovum to reach the uterus. I believe that in the human female it requires at least eight days, and in all probability the ovum is at a point where fruitful copulation is still possible for four or five days longer. At least the most favorable time for conception is not less than eight days after the beginning of menstruation.

In evidence of this take the woman whose religion deems her unclean from the first appearance of her period until the beginning of her second week. Yet no greater fecundity has ever been shown than among the Jews in every age and clime; this law like all those of the decalogue or those founded upon it, was one of exceeding wisdom and tended to the conservation of the species by preserving the woman from the dangers of extra-uterine pregnancy. In other words extra-uterine pregnancy is liable to occur under one or the other of the following conditions:

1st. When by reason of the destruction of the cilia in the Fallopian tubes the ovum is prevented from reaching the uterus.

2nd. When copulation occurs immediately preceding menstruation and the spermatozoa reach the ovary even before the rupture of the Graafian vesicle. This also applies to women who ovulate after childbirth without any menstrual flow.

Coming back to my case, the ovum was fecundated while passing through the intra-mural portion of the tube. Fixation occurred near the proximal end of the

tube. In the process of development the placenta extended in the direction of the least resistance; fortunately for the patient this was in the direction of the uterine cavity. An embryo which in the beginning was outside of the uterine cavity later entered the cavity. All the pain during pregnancy and the trouble at the end of the term, resulted from the abnormal point at which fecundation took place. Had fixation or in other words fecundation, occurred a little further out in the tube an extra-uterine pregnancy with rupture into the abdominal cavity would have been inevitable. That all this may be pure theory and without foundation I am ready to admit. Investigation in this line has in the last decade been neglected. One author quotes from another, Lusk from Flint and Flint from some earlier writer. No other scheme so fully accounts for the phenomena of reproduction either normal or abnormal and it calls for no violation of any natural law. Briefly stated it is:

1st. The human ovum is conveyed by the movement of the cilia of the tube from the ovary into the uterus. This process lasting from eight to fourteen days.

2nd. The uterus during this interval has been prepared for its reception and development.

3rd. The ovum on being fertilized after its entrance into the uterus at once becomes fixed. And all things being favorable the development of embryo goes on to term.

4th. That all departures from this law are pathological and not physiological, the exception and not the rule.

SPECIFIC VAGINITIS.*

JNO. G. CECIL, B. S., M. D.†

Several questions relating to different phases of this subject are of sufficient interest and importance to justify further consideration; in truth, it would well become the profession to continue to agitate this well worn theme until some more definite conclusions could be established than can yet be claimed. It is with this end in view that the suggestions embraced in this short paper, are offered, trusting that the discussion may crystallize our present knowledge into more definite shape.

Perhaps a simple enumeration of the possible sequelæ and complications that may arise from specific vaginitis will not be out of place here. There is hardly another disease in the whole catagory of human ills that can boast of such a progeny. A partial list comprises—inflammation and abscess of the vulvo-vaginal glands, vulvitis, endometritis, and endocervicitis, salpingitis, ovaritis, peritonitis, cystitis, pyelitis, nephritis, adenitis, gonorrhœal rheumatism, gonorrhœal ophthalmia, proctitis. Does not this list plead with burning eloquence the gravity, the importance of this disease to the human race, and for the untiring vigilance and zeal of the medical profession in grappling with it? And not only the medical profession but civil authorities as well? The social evil has always existed; judging the future by the past and present it always will exist. I believe that licensed prostitution, with governmental inspection in systematic and regular manner, and compulsory sequestration and treatment by competent physicians will do more to limit the spread of gonorrhœa than any other means yet suggested. It would require years and scores of years of continuous effort to accomplish very many visible results.

This is a contagious disease and must propogate by contagion, its control therefore ought not to be an impossibility, any more so at least, than any other contagious disease. I am forced to conclude that medical men are not as keenly alive to the terrifying consequences and possibilities of this disease as they should be. The popular fallacy that "a clap is no worse than a bad cold" has too many adherents in the ranks of the profession. This seems a justifiable deduction from the careless inspection of new and acute cases, the hasty prescription, the more hasty and imperfect directions as to the

*Read before the Clinical Society of Louisville.

†Lecturer on Gynecology, University of Louisville.

use of injections, douches, etc., and particularly the acceptance of a statement from the patient that the cure is complete, in lieu of a thorough and pains-taking examination of every surface or canal involved. A valuable clinical point in differential diagnosis between simple and specific vaginitis that is agreed upon by modern authorities is that urethritis or endocervicitis, or both, are always present in gonorrhœal vaginitis.

As to the pathology of specific vaginitis we are still in perplexity. For many years after the discovery of Neisser we made obeisance to his gonococcus, but at present it appears to be the consensus of opinion that something in addition to the presence of Neisser's bacillus is necessary to the development of gonorrhœa. What that something is constitutes the perplexing question. Experiments made by Neisser, Krausé, Löffler, Bouchard, Burner and others demonstrate the failure of pure culture of the gonococcus to produce gonorrhœa.

The question as to how long the specific virus of gonorrhœa may retain its activity in the genital cavities is one of exceeding interest and importance, and one to which I have seen no conclusive answer. This question is often put relative to a prospective marriage, or as to how soon after an acute specific inflammation of the vagina and urethra should a prostitute resume her avocation. It will be difficult to formulate a law applicable to all cases. Certain it is however that gonorrhœal virus of propagating activity may lurk in the various pockets and glands long after all subjective symptoms have subsided. Herein lies the particular necessity for a searching examination of every gonorrhœal patient before final discharge. This clinical fact is also the probable explanation of the auto-infection of puerperal women, a class of cases that make much work for the pelvic surgeon.

TREATMENT:

Under this heading it would be difficult, even if it were necessary to suggest anything new pertaining to medicaments. I am prepared to admit that many of the different lines of treatment at present in vogue are efficient. The success or failure of any particular method of management depends more upon the guiding hand and the strict adherence to directions explicitly given, than upon the medicine used. Many of the popular prescriptions and injections will be found satisfactory provided the details of management are faithfully carried out.

Given a case of acute gonorrhœal vaginitis, it is well to divide the treatment into three stages. First—in the initial stage of acute suffering with active inflammation, the treatment should be of soothing character, the injections of very mild solution and given in large quantity, nothing is preferable to corrosive sublimate in strength of 1 to 10,000 given warm, and with it an anodyne such as cocaine or morphine if necessary to relieve pain. Diluent drinks are serviceable and rest is imperatively demanded. Second—after the acute symptoms have subsided the treatment should then be more vigorous and active. The strength of the douche should be increased to 1 to 2,000 or 3,000 of corrosive sublimate and administered twice or three times in twenty-four hours. It is just at this point in the treatment of a case that the discipline necessary to a complete cure is likely to be relaxed—the suffering gone or relieved, the patient naturally concludes that strict attention to directions is no longer obligatory. Many cease the treatment altogether and so are only half cured, or really are not cured at all, but go to fill up the ranks of chronic or latent gonorrhœas. Another point that should be most strenuously enjoined is the proper method of administering the douche. The fountain syringe or douche-can should be used in order that large quantities may be given; the douche point should be of glass and should be immersed in a carbolic acid solution when not in use. The patient must be in the dorsal decubitus with hips elevated. The doctor ought to give the first douche himself and so instruct the nurse who is in charge of the case as to the exact detail of each subsequent douche. The glass point is introduced the entire depth of the vagina and with two fingers of the disengaged hand, every pocket or cul de sac, and the sulci between the vaginal rugæ are opened up or spread out so that the medicated wash reaches every part of the diseased surface. It is apparent that no woman can properly administer a douche to herself. After the injection a tampon of iodoform gauze is left against the cervix uteri. For the accompanying urethritis a pencil of iodoform is

left in the urethra, twice daily. Third—if chronic vaginal inflammation or cervical catarrah persist after a treatment carried out in thoroughness of detail as above indicated, it is probably due to extension of the disease into the cervical or uterine cavity, and attention is now directed to these localities. Treatment now to be efficient must be radical. Cervical dilatation followed by curettage with a sharp curette to the extent of destruction of the lining mucosa, or Schroeder's operation of excision of the cervical mucous membrane are indicated as the best methods of curing chronic or latent vaginitis due to gonorrhœa.

Management of specific vaginitis as above suggested will assuredly result in fewer cases that are pronounced incurable, and in fewer cases that by extension of the infection to the Fallopian tubes and ovaries, are relegated to the pelvic surgeon for permanent relief only after irreparable damage has been done.

SOCIETY REPORTS.

THE CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting of February 7th, 1893.

The Vice-President, Dr. J. M. Krim, in the Chair.

SPASTIC PARALYSIS FROM CENTRAL LESION.

Dr. W. O. Roberts: This patient is eight months old. At the time of its birth the mother had a hard and protracted labor and was delivered with instruments. She noticed soon after birth of the child that it did not seem to have any use of one arm, that it seemed to be turned or twisted to one side, the arm was abducted and rotated inward. Six months after birth (two months ago) the child was taken to a surgeon in a neighboring city, who said there was dislocation of the shoulder and a fracture of the forearm. He worked with it, put it into splints and had it under treatment for six weeks; the splints were removed after he went home. The family say that the arm is in much better condition than when this gentleman saw it. By examination now you will notice that movements of the elbow are very good, as are those also of the wrist; pronation and supination seem to be all right. But there is limited motion at the shoulder joint, and in examining the axilla you will find that the pectoralis minor muscle is tightly contracted. The hand on the affected side is very much smaller than that of the other side and the fingers are in a flexed condition, but can be straightened out. There is little or no difference in the size of the two arms.

A peculiar feature of the case is that the anterior fontanelle is entirely closed, which rarely happens at the age of eight months.

DISCUSSION.

Dr. T. P. Satterwaite: I think the case is one of spinal trouble. It is not an uncommon thing for children to be born with paralysis of some of the muscles. There was a gentleman in this city born with paralysis of the deltoid muscle, and that was the only muscle in the arm that was paralyzed. When I saw the the case the man was about 35 years of age, and had never had any use of that muscle. This case is one of central nerve lesion.

Dr. W. O. Roberts: The doctor who saw this case claims to have reduced two dislocations and set a fracture. There is now apparently no evidence of a fracture having existed, no callous or anything pointing toward fracture, and it has only been two months since he first saw the child.

Dr. J. G. Cecil: I hardly know what to say about the case; the history is so uncertain; having to depend on the family to give an account of an obstetrical case makes it a very unsatisfactory and uncertain sort of history. It struck me at first that it must have been simply a dislocation of the shoulder, which had been produced

in the delivery. As you know we sometimes have difficulty in the delivery of the shoulders even after the head has passed with comparative ease. I saw in consultation a case not very long ago of forceps delivery, in which there was an occipito-posterior position, delivered with forceps after pretty hard effort, and the shoulders failed to rotate into the antero-posterior diameter of the outlet making delivery very difficult, so much so that both my consultant and myself thought it very probable that there would be injury to the shoulder joint but fortunately even although we had to use considerable force in the delivery of the shoulders, no injury was done. I can very readily see how in this case there might have been detention of the shoulders, and a blunt hook could have been introduced in the axillary cavity and the consequent injury from this procedure. But if there has been a dislocation of the shoulder, I fully agree with Roberts that there ought to be more evidence of it now. The reduction of a shoulder joint dislocation in a child, after six months standing, would most certainly show more evidence than we find here.

The question as to whether it is central lesion or spinal trouble is one that seems to me to be in a good deal of doubt. I thought from the peculiar crease upon the child's head that possibly it might have been the result of forceps injury, but the mother says the head was not marked at all by instruments. It is also unusual that the anterior fontanelle should be entirely closed at the age of eight months, yet I cannot see how that would have any effect upon the subsequent history of the child, except by possible interference with development of the brain. The history is so uncertain that it seems to me it would be very hard to get at a correct diagnosis in this case.

Dr. W. O. Roberts: I cannot think that there was any dislocation, because had there been the arm would not have been brought close to the side twisted in this way, it would have stood out more. It is a case of spastic paralysis from central lesion. I think the physician who treated the case simply improved the position of the arm by stretching the contraction. Then again the wasting of the hand and drawing in of the fingers would indicate central trouble.

As to treatment, now that is a point of considerable interest as to whether passive motion, massage and stretching these contracted muscles will overcome the rigidity, or whether it would be better to divide the muscle in the axilla. My idea is the best plan of treatment would be passive motion with electricity and massage for a couple of months, and then if the trouble is not overcome, divide the muscle and stretch it. That will give motion to the shoulder, then of course the muscles of the arm and forearm will have to be tested with electricity to see whether there is any paralysis.

Dr. J. G. Cecil presented "Specific Vaginitis" as the subject for the regular discussion (see page 410.)

DISCUSSION.

Dr. F. C. Simpson: (visiting) I no not think there is any question about numbers of these cases going on for months from no other cause than negligence in treatment. As Dr. Cecil says the difficulty is to get at all portions of the vaginal canal. I believe this can be done if the case is properly managed. Physicians, I believe, are often very negligent on this point, which may account for numbers of cases being reported cured and afterward develop some pelvic trouble. I think it is advisable in these cases to take a sample of the discharge and have it microscopically examined to see whether all the gonococci have been destroyed. The trouble might apparently be cured, still from lack of thoroughness, if any of the gonococci remained in any part of the canal or in the uterus, there will be a return of the symptoms, possibly with such severity as to require operative interference.

Dr. P. Gunterman: Dr. Cecil has said about all there is to be said upon the subject. I do not agree as far as my experience and reading goes, with the statement that urethritis is always present in specific vaginitis, but I do believe that cervicitis is always present, which I believe should be treated the same as vaginitis with douchings, and then you can make local applications to the cervix carrying them up into the body of the uterus if necessary. A solution of corrosive sublimate I think is considered best by all authorities for use as douche in these cases, weak at first and the strength increased afterward. I agree with Dr. Simpson that it is advisable in these cases to have

the secretion microscopically examined and think it should be done by a very competent man, and even then there is doubt in my mind whether it can be proven in all cases that the vaginitis is gonorrhœal in origin, as there is another coccus which so nearly simulates the gonococus that they cannot always be differentiated.

Dr. L. S. McMurtry: I think Dr. Cecil's paper is most opportune indeed. Until very recently the profession has regarded gonorrhœa in the female as a trivial disease. There is a large proportion of the profession, even at the present time that, make no discrimination between leucorrhœa of simple catarrhal character and specific vaginitis, all cases being treated as leucorrhœa. It seems to me that the time has come when more attention should be directed toward the prevention of the severe sequelæ of gonorrhœa—prosalypinx, ovaritis, suppurative peritonitis, which require abdominal section—by giving careful attention to its treatment in its incipiency. It is rather exceptional for patients with gonorrhœa to seek medical aid early in the attack. I was greatly pleased to see that Dr. Cecil has interpolated on the back of one of his pages the sentence that "specific vaginitis as a rule is accompanied by urethritis" and was surprised to hear such a close observer and profound student as Dr. Gunterman say that he did not agree with the essayist in that particular. It has certainly been my observation that specific vaginitis is invariable accompanied by severe urethritis.

The greatest defect I think in the treat- of specific vaginitis, as mentioned by the essayist, has always been that the physician treats these cases in a very desultory manner, advising the patient to use a vaginal douche, yet does not instruct her how to do so properly. It seems like a very simple thing to discuss at length, but it is a fact that very few practitioners inform a woman as to the position they should assume in taking a vaginal douche; that sitting over a basin and using a syringe forces down all pelvic organs preventing access to the folds of the vagina. I think a fountain syringe preferable to any other for this purpose. Instead of sitting over a basin the patient ahould be in a semi-recumbent position with a rubber cloth such as can be found in almost every house under her hips, which should be slightly elevated, then the nozzle of the syringe can be introduced into the vagina so as to reach all the surface. I have very grave doubts as to whether any woman is competent to treat herself by vaginal douches for gonorrhœa, efficiently. The treatment of this disease is the same as the treatment of an abscess, and ought to be so regarded. I am losing my faith in antiseptie injections to cure gonorrhœa. I doubt very much whether 1 to 10,000 solution of bichloride of mercury can make much impression upon virulent gonorrhœa; I believe that everything which is accomplished is done by flushing and by drainage. If you use simply hot water, placing the patient in the proper position, using two fingers in the manner described by Dr. Cecil, thoroughly flushing the vaginal surface, much good can be accomplished; and the oftener it is done the better. If you have the patients under control and can get them to devote themselves to it, I think the vagina should be flushed with hot water from four to six times in the twenty-four hours during the acute stage; then pass a piece of iodoform gauze up to the cervix so as to encourage drainage all the time in the intervals between—if this line of treatment could be followed out our results in the acute stage would be more satisfactory. Of course this is sometimes impracticable, and as long as treatment is neglected or imperfectly carried out, there will be a great many cases followed by endometritis, salpingitis, and peritonitis.

There is one point upon which I must differ with the essayist; that is, I do not believe we ought to open up the cervical canal and interior of the uterus until the indications for it are positive. By opening up these surfaces we may readily spread the infection over a field not yet invaded.

Dr. J. G. Cecil: In the paper I divided this subject into three stages, and indicated treatment accordingly; for the first stage I suggested that the solution of bichloride should be very mild 1 to 10,000 until after the acute symptoms had subsided, perhaps a week or two, then to attack the sub-acute condition with a stronger solution, 1 to 2,000 or 1 to 3,000, and after that the third stage.

Dr. Geo. W. Griffiths: Do you not use acetate of lead and the other drugs

that are known to produce good results in these cases?

Dr. J. G. Cecil: I stated that I believed the successful treatment of gonorrhœa depended more upon thoroughness of detail in the management than upon the medicine used; that I was certain in my own mind that nearly all of the popular prescriptions would be followed by success if directions explicitly given by the physician were thoroughly carried out by the patient and her nurse. I have confidence in a good many drugs, and simply referred to corrosive sublimate as probably the best.

Concerning the douche point: I really do not think it makes much difference what kind of a point is used, or in what direction the current flows, but the important point is to get the medicated wash, whatever you are using, to every part of the diseased surface, and that is why I dwelt upon so simple a matter as giving a douche. It is a well known fact that if you allow a woman to squat down over a vessel and give herself an injection with an ordinary syringe, with any kind of a douche point, whether the current runs one way or the other, there will likely be parts of the vaginal surface that will not be reached at all, hence chronic gonorrhœa will result, and it will exist indefinitely unless a thorough line of treatment is persevered in. When a woman sits down over a vessel a portion of the vagina is practically shut off, and this is why I described so minutely the manner of taking two fingers and spreading out every part and fold of the vagina, having the patient in the dorsal decubitus with the hips slightly elevated; in this way you can be sure that the solution is carried to every part of the vaginal tract, and unless done in this way I do not think you can be positive that the douching has been thoroughly accomplished.

I do not know what proportion of cases of salpingitis, pyo-salpinx and pelvic peritonitis or abscess are due to gonorrhœa, directly or indirectly, but any one reading over a list of cases where trouble has been taken to ascertain whether or not there was the previous history of gonorrhœa, it is simply astonishing to find how many of such cases give such a history, and for that reason it seems to me the importance of this matter can hardly be exaggerated. I think Dr. McMurtry, and all men who do pelvic surgery, will appreciate the importance of prevention. Certainly it is better if we can cure a case, and I admit all he says about the difficulty, and for that reason I took occasion to run off on to side-issues and say that I thought government control ought to be established over prostitutes as they are the ones who promulgate the disease. We may not be able to exterminate it, but if we can prevent it becoming chronic and extending to the upper and more remote genital passages, we are doing a great service to humanity.

The subject of the suppression or cure of this disease is one I have often thought of, and one that I am glad to see has very recently been seriously agitated. In yesterday's *Record* I noticed an editorial on this subject, and in the last week's *News* another editorial upon the recent article of Neisser as to the proper management, control and suppression of gonorrhœa. I do not know how to express in words what the importance of this subject is to the human race at large. When we see all of this train of complications and after results of gonorrhœa, we certainly cannot exaggerate it. I believe most of us will admit that we are often very negligent in the treatment of cases of gonorrhœa. Gonorrhœa in women is infinitely more serious than it is in men and we all know from recent discussions, if we have not known it before, what terrible results follow the neglect of proper treatment in the male, but in the female it is infinitely more so. Consequently I believe a continued agitation of the subject especially called for, and by bringing it to the minds of the medical public generally, good results will come.

In regard to the point mentioned by Dr. Gunterman: I think he will find recent authorities all agree that urethritis is an invariable accompaniment of specific vaginitis. That is really the only differential diagnostic point that can be made clinically, between simple and specific vaginitis.

I do not know whether Dr. McMurtry in his remarks concerning the treatment of cervicitis caught my meaning exactly, so it will perhaps be well to state it over: If he will recall the paper, I stated that after you had treated in an active and vigorous way the sub-acute symptoms of gonorrhœa with douche and with an iodoform pencil

in the urethra; if after all that you found that the gonorrhœa or vaginitis continued, an examination in that case would likely discover a cervical catarrh. After you have used the douche thoroughly for a length of time sufficient to cure; after you have used the iodoform plug in the cervix in order to favor drainage, then to cure the cervical catarrh which keeps up the specific vaginitis, I favor as the third stage of treatment a vigorous attack upon the cervical mucous membrane. My observation in the treatment of gonorrhœa, quite extensive I may say, because I have had the opportunities for six or seven years in the clinic at the University of Louisville to see a great many cases of cervical catarrh, leads me to believe from the class of patients presenting, that they were generally gonorrhœal in origin, and that ordinary treatment did them but very little good. I am thoroughly conscious of the fact that it is dangerous to invade the uterine cavity unless it is urgently demanded. I am equally certain that cases of cervical catarrh of the kind I have just mentioned did not yield to vaginal treatment, and am pretty well satisfied that a thorough destruction of the cervical mu cous membrane, which as you know is studded with follicles, is necessary in almost every case to effect a cure.

Now with proper precautions I believe that curetting can be done without fear of further infection. I think the woman is in greater danger of infection from extension of the disease to the higher cavities, the womb, tubes, etc., by allowing the catarrh to remain, or by temporizing with it by medicated washes, etc., than if you, under the proper precautions, use the sharp curette. I have seen such results from the use of the sharp curette in the cervix —in fact I do not remember ever to have seen a bad result—that I am inclined to advocate this treatment for the relief of all cases of obstinate cervical catarrh, by this means getting rid of the disease with the destruction of the mucous membrane.

Dr. J. M. Krim: Do you make any application to the surface after curetting?

Dr. J. G. Cecil: I do not believe any application is necessary; further I do not think any curetting short of the destruction of Naboth's glands will cure the case, as gonorrhœa may lurk in these glands and nothing short of their complete destruction will have a permanent effect. However it is not a bad plan to follow curettage with a caustic like nitrate of silver.

Dr. J. M. Krim: By doing this it would certainly seal the raw surface and prevent any further infection from gonorrhœa. I think in these cases plain hot water for douchings without any bichlorides will do just as well. I have used bichloride solution in the male for gonorrhœa of strength 1 to 10,000 with no bad effects as far as the injections were concerned, but I never found that this treatment was any more successful than plain hot water.

Reproduction of Printed Matter, Engravings, Etc.

The *Moniteur Industrielle* gives the three following methods: M. Breton exposes the face of the print to be copied to the vapors of iodine, and then applies it face downward to a polished zinc plate. After contact for awhile the print is removed. The zinc is then printed from exactly as though it were a prepared lithographic stone. M. Balagny reproduces leaves of books, etc., by placing under each leaf a film of sensitized gelatin and exposing it to the light. The gelatin film is then used to print from exactly as in the carbon print process. Finally M. Ginestet, of the Department of Public Works, of Paris, soaks the page of print, the design or drawing in acidulated water for awhile, and after draining off, applies it to zinc or lithographic stone. After contact the design is removed, and the zinc or stone printed from in the usual way.—*Ex.*

For Cementing Iron.

The following mixture for cementing iron is strongly recommended: Equal parts of sulphur and white lead, with about one-sixth proportion of borax, are the constituents of the mixture, and the three should be thoroughly incorporated together so as to form one homogeneous mass. When the composition is to be applied it should be wetted with strong sulphuric acid, and a thin layer of it should be placed between the two pieces of iron to be connected, these being at once pressed together. This cement will hold so firmly as to resist the blows of a steam-hammer, and dry so completely in a few days as to leave no trace of the cement, the work then presenting the appearance of welding.—*Ex.*

CORRESPONDENCE.

MEDICAL COLLEGES AND SMALL CITIES.

MR. EDITOR:—It is both a significant and deplorable fact that the great cities of the United States have the fewest Medical Colleges both relatively and absolutely. New York has three, Philadelphia three and Chicago three. Yet such small cities as Louisville and Cincinnati are blessed with four each, and such small villages as Ft. Wayne, Ind., and Keokuk, Iowa, have one each. Joplin, a little hamlet out in Missouri, did, for a short time, sport something which the good-natured inhabitants pointed to with pride as their medical college, but the cold and unfeeling Illinois Board of Health sat down on it and Lo! it was not. As Artemus Ward said: "Why is this thusly?" Surely if New York, Philadelphia and Chicago, with their three million and more of population, centered in states representing, in the aggregate, nearly ten million people can get along with three schools each, small villages, located within the glare of their electric lights, ought not to consider the world totally bereft of knowledge if they should be found with no medical college at all.

There is a great tendency in both the South and West to multiply schools of all kinds. It does not occur to them to concentrate capital and energy at a few large centers of population where the emoluments of business are so large and gratifying that both talent and superior attainments can afford to be found. Vanity and avarice alike encourage this state of affairs.

We have no hereditary titles of nobility in this country. In the West and South the rage for titles is almost epidemic. All cannot be justices of the peace or "squires." There are a few of the rising generation who were not in the army and who do not belong to the G. A. R., hence fail to reach the proud distinction of Captain or Colonel. But there are one or two titles which are as common as walnut hulls around a country school house. These are Doctor and Professor. Hence the great demand for something cheap in the way of a school by those who aspire to the title of doctor, and the eagerness to supply this demand by those who wish to stagger along under the learned appellation of professor. True the "hoss" doctor, the "writin'" master and the "deestrict" school teacher are all called professor by an admiring and accommodating public, but knights of the fleam and the ferule receive their accolade on account of useful knowledge which is indispensable to their calling. Is the veterinary ignorant? then some old horse may die from lack of that help which he ought to be able to give, and his rustic owner lose forty or fifty dollars. Is the young teacher lacking in knowledge of the three R's? then some budding genius may be nipped by the frosts of ignorance because not properly tutored by the rising pedagogue. Not thus is the average professor in the village medical college. His one positive and enduring attribute, which stands out in bold relief, is not unfrequently a large, thick, dark stratified quality of ignorance. True, he now and then tries to hide it from the senior class of two or three, with a large translucent label of conservatism—and sometimes succeeds. Then when his classes graduate consultations are multiplied even if the multiplier be not very large.

By being known as a teacher in a college, people who can not make distinction between the little one-horse institutions with a graduating class of two and a matriculation of some twenty-five or thirty, and some great and amply endowed school like the University of Pennsylvania or the Michigan University, suppose that a Professor is a Professor anywhere and are thus often led to believe that a great man resides among them.

But the advancement of mediocrity into a large practice or into places of honor, and then fastening on a title like tying a tin can on a dog's tail, is not the worst nor the only evil inflicted by the multiplying of opportunities for superficial students to slip into practice easily. Cheap doctors are made abundant, and the struggle for existence becoming sharper and sharper, competent men are discouraged, and stay out of a profession

that exhibits such a contest between bread-and-butter scramblers and scientific enthusiasts who look upon sordid motives as always subordinate to the pursuit of truth, and the evolution of methods tending to ameliorate the ills that flesh is heir to.

It is the great number of small, weak, insufficiently endowed, meagerly attended and poorly equipped medical schools that has kept medical education at a stand still for so long, and that has set a standard of attainments for graduation so low that a diploma from most of them has no more force and commands no more respect than a patent medicine certificate. It is the mighty array of these schools, whose name is legion, that has kept off the statute books much needed legislation regulating the teaching and the practice of medicine.

In a condition of society such as existed a few decades ago, there might have been some excuse for the existence of inferior medical schools in a few of the smaller cities. The country was filling up rapidly and the sparsely settled districts needed a supply of cheap and ready doctors. Opportunities for medical education did not then differ so much in the larger from what they were in the smaller cities. The sciences auxiliary to medicine were neither developed, studied nor taught as they are now. Clinical instruction was almost unknown,and obstetrics was taught in a very imperfect and theoretical way only. Didactic lectures supplemented by a course of reading in text books constituted the curriculum in almost universal enforcement. This regime could be carried out in a city of moderate size as well as in a more pretentious one.

But modern medicine as it is taught, has enlarged its field, changed its methods, improved its facilities and added to its curriculum until great centers of population and immense moneyed endowments are absolutely essential to meet the much greater demands which our rapidly advancing civilization is constantly enhancing.

There is another and graver condition of things brought about by trying to organize and equip a medical school in every little place that has a post-office and a railroad. It gives our homœpathic brethren the power to get a higher average in the attainments of their graduates, and often we have to blush for ourselves instead of our irregular competitors. They are comparatively few in numbers, hence can only afford to support a medical school in a large city like Philadelphia, New York, Boston or Chicago. In cities of this size their clinical advantages are great; and, having to compete with the University, Jefferson, The Rush or Harvard, they are compelled to set an equally high standard for graduation. Thus it happens that the alumnus of a school like the Hahnneman of Philadelphia with its three years course of study, and the clinical advantages of the great hospitals of the city like Blockley and the Pennsylvania, turns up his nose, and justly too, at the graduate of some little two year institution located at Grubses' Mill or some other little Southern or Western town, though it be ever so "regular." It would be far better for the profession and for mankind in general, if a law was passed authorizing any man after he had practiced five or ten years to take his choice of titles as Col., Capt., Prof. or "Squire."—In order to be perfectly just we might save the title of "Squire" for the midwives.—Under such a regime as this the rage for titles, the hunger for artificial distinctions might be approved without organized robbery. For when a lot of old bald-headed antediluvians in some little town get together and organize themselves into a mutual admiration society and call it a medical college, they pass one another on the street as often as possible thereafter, and spread their ears out like a palm-leaf-fan to catch the greeting: "Good morning Professor! Fine day Professor!" Then the Professah bows and smiles, and gets up against something and rubs himself—he feels so good. If the gratifica ion of childish vanity was the only result of these cheap John schools there would not be so much to regret. But when men take a young man's money and are unable to do more in the way of tutoring than mix a few vulgar anecdotes with some ancient history and a few quotations from the scriptures; when the clinical advantages consist possibly of a fracture or two, a case of phimosis and a few cases of pediculi and intermittent fever, they also rob students of their time.

Let us have fewer Professors and more teachers. Let us have fewer schools and richer endowments. Let us keep the advancement of scientific medicine more to

the front and ourselves more in the back ground. Let us work more and quarrel less. Let teachers be selected for what they have done and not for what some rich relative *can do*. Let schools be organized for the benefit of the student and those he must treat, and not to push forward some scion of wealth or some master of medical skull-duggery.

Then no respectable sheep will be ashamed to see his skin converted into a diploma. Then may the teaching and licensing power be entrusted to the same body. Then will the Irregular lamb and the Regular lion lay down together—with the lamb inside—Selah!

Petersburg, Ind.

NEW YORK LETTER.*

About a month ago, at a meeting of the Section on Obstetrics and Gynecology at the Academy of Medicine, Dr. E. H. Grandin read a paper on the "Treatment of Purulent Puerperal Peritonitis." The exceedingly high death rate of this disease added interest to the interesting paper presented. Dr. Grandin said that fifteen years ago it was the practice to treat all cases of puerperal peritonitis with opium. He followed out this plan of treatment in several cases and all died. Later on the saline method of treatment prevailed, and he tried this in a considerable number of cases with a mortality similar to that he got from the use of opium. During the last few years he has resorted to laparotomy, and in a series of four cases has saved two of the patients. In all the cases symptoms of peritonitis came on soon after confinement, and his earlier experience had taught him that it was useless to resort to opium or to the saline treatment.

In the first patient upon whom he operated, he found a large abscess in the left side of the peritoneal cavity and communicating with the uterine cavity. This was complicated with general peritonitis. He washed out the cavity and drained it by means of a tube through the uterus. This patient recovered.

The next two cases had general purulent peritonitis and both died in spite of the operation. The fourth case was of the same nature, but fluctuation could be felt above Poupart's ligament on the left side. The patient survived the operation and at present is doing well.

Dr. Grandin considers that fifty per cent. is a high mortality, but that it is far better than the results obtained under the old method of treatment. He said that the high mortality of this disease was due to general systemic infection which preceded the peritonitis. Notwithstanding that a patient's chances are very small when purulent peritonitis sets in, it is well to do an abdominal section as the purulent collection may not be general.

In the discussion which followed Dr. Van Ramdohr said that it was certainly right to evacuate pus wherever it was found, but that in general purulent peritonitis the patient would die anyway, and if it were not purulent such remedies as alcohol would pull her through. A general purulent peritonitis cannot be diagnosed from one that is not purulent.

Dr. Edebohl believed all that the author of the paper had said. He has lost the patients upon whom he performed cœliotomy for general purulent peritonitis; it was not from the effects of the operation, but from the peritonitis.

Dr. Collyer thought that the author was correct in his views, and that his paper would set the profession thinking on this point.

Dr. Garrigues said there was no possible way of telling whether or not a peritonitis were purulent, and if it were purulent, whether or not it were local; of course, if it were local the pus should be evacuated by surgical procedure. He mentioned his list of thirteen cases of general puerpural purulent peritonitis, all of whom he treated with opium and succeeded in saving seven of them.

Dr. Grandin closed the discussion by saying that in the series of cases which he mentioned, there were collections of pus throughout the general peritoneal cavity, hence it would have been impossible to

*Special Correspondent to The Medical and Surgical Reporter.

cure the cases with alcohol, opium, or salines; that these same remedies would be of no service in a localized peritonitis, and since, when a diagnosis of general purulent peritonitis was made, abdominal section might show the process to be local, he thought that one was justified in opening the peritoneal cavity.

* * *

At a meeting of the Section on Surgery at the Academy, some time ago, the president, Professor Joseph D. Bryant exhibited a man whom he cured of a large aneurysm of the external iliac artery. The patient was thirty-five years old, with a syphilitic history. Two years ago while supporting a heavy weight on his right side he felt a boring pain in the right side of his abdomen, and soon there developed a pulsating tumor in this locality. The man had been treated by other surgeons before coming to Dr. Bryant, one of whom introduced twenty yards of fine wire through a canula, for the purpose of forming a clot. Treatment by compression was also tried but both of these methods failed and the tumor continued to pulsate and to give pain from its pressure effects on the lumbar nerves.

The patient came to Dr. Bryant about seven months ago. At that time the tumor was the size of a large cocoa-nut, distinctly showed an expansile pulsation synchronous with the ventricular systole, and a bruit could be heard over the tumor and transmitted down over the course of the femoral artery.

It was at once seen that the patient's condition was serious and it was decided to try McEwen's method for the cure of the aneurysm. Several long steel needles were made, varying in diameter from one-half to one millimeter. A couple of the smaller needles were first introduced, until their points reached the opposite interior wall of the sac. With each pulse-beat the needles were moved, their points irritated the interior of the sac and thus set up an inflammatory process, and from this a white thrombus formed. The location of the irritation was changed every ten or fifteen minutes until the whole lining of the sac had been gone over. These needles were left in for twenty-four hours, but no change in the tumor seemed to result. A week later two of the larger needles were inserted and left in for forty-eight hours. In a few days after their removal, the bruit lessened and gradually disappeared, the tumor diminished in size, the pulsation gradually became less pronounced and the man ceased to complain of pain.

This case has interested the surgeons of the city considerably, as not many cases of cure by McEwen's method have been reported, and because of the high mortality attending aneurysms in the large cavities.

After-Effects of Chloroform.

Luther (*Münch. med. Woch.*, January 3, 1893), says that changes are found in the kidneys after death by chloroform, however produced. He says that almost after every administration, especially if prolonged, albumen and casts appear in the urine. The author has found that (1) the urine was normal when no after-effects, such as vomiting, etc., were present; (2) of many cases examined, the after-effects were most marked in the single case in which abnormal constituents were found in the urine; (3) albuminuria and cylinduria go hand in hand, and disappear after a few days, and (4) the casts are mostly hyaline. He concludes for these reasons that (1) the use of chloroform should be limited to cases where it is necessary; (2) in every case before prolonged narcosis the urine should be examined, renal diseases being a more important contra-indication than heart disease (except fatty heart); (3) chloroform narcosis should be restricted in the case of the pregnant and lying-in, and it should be absolutely avoided in eclampsia, since it must be prolonged, and the kidneys are nearly always diseased; and (4) mild diuretics are of value in the after-effects of chloroform.—*British Med. Journal.*

Glycerin Jelly for Mounting

Microscopical preparations is best prepared, according to J. E. Huber (*Phar. Centralh.*), by excluding water altogether. Macerate 1 dram of gelatin in 12 drams of glycerin, and after 12 hours effect solution by the aid of a water bath. The specimens to be mounted are first soaked in dilute and then pure glycerin. They are then placed on the slide with the least possible dilute glycerin and then covered with the liquified jelly.—*Western Drug.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MARCH 18TH, 1893.

EDITORIAL.

CHOLERA THIS SEASON.

Preventive Medicine and the Germ Theory are the crowning triumphs of the nineteenth century.

While the germ theory has taught us but little in the way of therapy, it has placed the science of prophylaxis on an eminence never before attained. The ounce of prevention has come to be worth *several pounds of cure.*

In view of the possible, nay probable, epidemic of cholera during the hot season just ahead of us, it behooves us as a people, both in the aggregate and segregate, to preach, practice and enforce all the means of prevention within our knowledge or power. This is a form of charity in which we need not fear to let our right hand know what our left hand does. Let those in large cities whose duty it is to look after the health of the inhabitants see to it that the cities are put in the very best possible sanitary condition. In this connection the words clean and sanitary are synonyms. Let the fat alderman "with fair round belly with good capon lined" stop the amber stream of lager long enough to consider for a moment the welfare of the tax-payers whose money he delights to spend.

Let the small towns clean up their yards and outhouses. Let them abolish the stinking pig sty whose odor exhaleth to heaven, whose muddy floor offers a free soil, a good culture medium and fine homestead law for any wandering cholera spirillium or diphtheritic coccus that chooses to stake off a claim and "prove up" in a quarter section of such inviting territory.

The water supply of both cities and small towns should be looked after with scrupulous care, and where the source of supply is likely to be contaminated, the people should be instructed to boil all that is used for drinking purposes.

With our present knowledge of the comma bacillus, and how to destroy it, we can act with intelligence and effect in our efforts to ward off the coming pestilence. Now is the time to act. Now is the time to get scared. "Let us act in the living present."

There is reason to fear an epidemic from either or both of two sources. The germs of last year may lie dormant till favorable weather appears when they can get a foothold that can scarcely be eradicated. Again, infection may come along the lines of travel and commerce and easily slip past the scattered cordons of quarantine.

But in order that there may be no mistake made when cholera does appear, or when diseases which simulate it make their presence felt in our midst, all physicians in commercial metropolis, at least, should make themselves familiar with both the natural history and the bacteriology of the disease in order that a panic may not grow out of some simple case of belly ache; and, on the other hand, that no precautions to avoid contagion may be neglected in the presence of the real disease under the impression that only a case of ordinary cholera nostras is to be conquered.

Sternburg has lately shown that sunshine is one of the very best destructive agencies which the comma spirillium can be exposed to. Let us turn on the sunlight. It is both cheap and plentiful.

TRANSLATIONS.

A Report of Purperal Cases of the Munchener Franenklinik, 1877 to '91.*

According to Dr. Madlener, during the years 1887 to 1891, there were 4,000 pregnant women cared for; 3,944 of these were delivered at the Maternity, 55 were admitted during or immediately after labor; 27 died, a mortality of 0.67 per cent. Ten died of puerperal infection, 5 from rupture of the uterus, 3 from eclampsia, 2 from access of air into the uterine veins, 1 from sublimate poisoning, 2 from acute anæmia, 1 from carcinoma of the ovaries, 1 from pneumonia, 2 from cardiac trouble. Death occurred in 3, during labor, 2 immediately after completion of labor, 22 during the later period of the puerperium.

In the 27 fatal cases there were 13 operated upon. Of the 10 infected cases, 2 can be excluded since the infection took place before they were admitted.

The rules for the disinfection of the patient are: First, bath, then douche and enema with the use of plenty of soap and a 5 per cent. solution of carbolic acid, followed by vaginal injection of 1 metre of sublimate solution of 1 to 1,000. Before examination the hands and forearms are washed and brushed for 3 minutes in warm water, then 1 minute in 5 per cent. of carbolic acid solution, special attention being given to the nails; lastly, the hands are again washed and brushed in a sublimate solution of 1 to 1,000. Lysol has been found unreliable in these cases. During the labor injections are used only when strictly indicated; in normal labor irrigation is not used. After instrumental delivery the vagina is washed out with sublimate solution of 1 to 1,000. This is also done where intra-uterine manipulation may become necessary. Hot douches minus the sublimate solution are often used. The author speaks, in detail, of various methods for disinfection used in all the German Maternities, which show but very little differences. It is notable, however, that those who have a rise of temperature are not isolated and have no separate nurses. On the other hand, however, they have their own vaginal tube, thermometer, catheter and bed pan, and are instructed to wash themselves. Madlener finally gives an explicit history of the fatal puerperal cases. 6 cases suffered from metro-lymphangitis ; 1 case from thrombus producing metro-phlebitis; 1 case showed symptoms of both; in 2 cases it was impossible to find either a lymphatic or venous complication. In these cases there had been great anæmia following placenta prævia. He finds that the above cases followed a distinctive course. The metro-lymphangitis proved fatal in from three to fifteen days; clinically peritonitis seemed to be the first symptom,

*Translated for the MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

fever being high, showing very little remission. Chills were noticed in 4 out of 6 cases, pulse usually rapid, never less than a hundred. It is rather the rule than the exception to find ulcers at the entrance of the vagina; the lochia were fetid. In the metro-phlebitis cases there was an absence of the peritonitis symptom, fever began without a chill and showed no remission. The chills set in a week after, taking at times the remittent type and at other times the intermittent. The length of time in illness was forty-seven days. In the 5 cases of rupture of the uterus, 3 were due to violence and 2 were spontaneous. The first resulted from trying to produce version; four times the rupture was complete and once incomplete. Eclampsia was seen eleven times, 3 women died, a mortality of 27 per cent.; that of the children was 46 per cent. The fatal case of sublimate intoxication followed seven vaginal douches of a hot sublimate solution of 1 to 1000, which were given ante-partem to hasten labor. It was a case of artificial induction of labor.—(*Much. Med. Abhandl.*, iv 2, 1892).

A Rare Case of Injury During Labor.*

Dr. Opiering (*Centre. Bl. f. Gynæ*) reports the following case:

In the Schauta clinic of Prague, a primipara of 41 years, sustained during delivery a perforating wound between the rectum and the vagina, without injury to the perineum. The pelvis was normal, the vagina remarkably contracted. In spite of good labor pains, which had brought down a segment of the head, it failed to make any further progress. The head being in left position, a right episiotomie of about three centimetres was made. The next labor pain was followed by sudden bleeding from the rectum, and the right hand of the fœtus appeared in the anus as far as the elbow, without however, injurying the perineum. After reposition of the arm and birth of the child, the examination of the vagina showed a tear extending its entire length from the columna. The tear extended in its middle portion into the rectum about a hands breadth. Prompt healing followed the tamponing of the vagina.

*Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

The Treatment of Fracture of the Patella.*

Paul Klemm has used the following treatment for the last five years, which he reports in the St. Petersburg *Med. Wochen.*

Soon after the admission of the patient, at and around the knee-joint, massage is used. He places great stress in massage being particularly directed to the central portion of the fracture in order to increase the lymphatic and venous circulation. After the massage the joint is wrapped in cotton and then a dressing of adhesive plaster, which exercises a certain amount of pressure upon the intra-articular extravasation at the same time keeping the fragments of bone coaptated. The extremity dressed in this manner was then placed in a fracture box and moderately elevated. After three or four days the bandage was removed and the leg again thoroughly massaged. From this time on it was massaged daily, and after two weeks passive motions were used, the patient encouraged to elevate the leg with the knee extended. Between the third and fourth week the patient was encouraged to walk around the room with the aid of a cane, and the beginning of the sixth week usually discharged. Bony union was never met with; there was always a tense, fibrous uniting band which, however, did not interfere with the action of the knee-joint. In all cases there was complete active ability to extend as well as flex up to 50 degrees.

The Treatment of Abortion.*

E. Eckstein, of Teplitz, gives a report of 66 cases of abortion in Martin's clinic, in Berlin, all of which resulted favorably. The author recommends the instrumental treatment as the only rational method, while the tamponade should be used only in such cases where there is insufficient dilatation of the cervical canal. In cases where there is sufficient dilatation, prompt removal of the uterine contents should be practiced. In cases of five months and upwards the patient should be treated the same as if she were at full term; should, however, fever be present, due to decayed material in the uterus, this should be promptly removed and the uterus curetted. Ergot is given only after the uterus is emptied.—(*Schmidt's Jahrb.* Bd. 237, No. 1)

*Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

ABSTRACTS.

FIVE CASES OF LAPAROTOMY PERFORMED ON PATIENTS OVER SEVENTY YEARS OLD.

J. Rutherford Morison, M. D., says:—Long lists of successful ovariotomies can no longer serve any good purpose, for it has been proved that the mortality of ovariotomy should not exceed five per cent. Sir G. M. Humphry long since pointed out that in old people repair and recovery are likely enough to follow major operations. This is true of abdominal section—a fact not sufficiently recognized. The author's list includes all the patients over seventy years of age, on whom he had performed abdominal section, five in number. Four of them had ovariotomy successfully performed. Three of these are well and active at the present time. One died nearly two months after operation from the results of appendicitis. The fifth recovered from an exploratory abdominal section made to ascertain the nature of, and to treat if possible, an abdominal tumor of doubtful character and origin.

Case I., 1890. A widow aged seventy, with a cystic tumor in the abdomen, which was distended to about the size of a six months' pregnancy. Operation on Dec. 22, 1890. A broad ligament cyst was exposed, tapped, and enucleated after dividing the peritoneum covering it. The hemorrhage was arrested by tying each bleeding point as exposed. A large raw surface was left, over which the stripped peritoneum was laid. The operation occupied one hour. Drainage was employed for three days. The patient recovered so rapidly that she was allowed to get up on the tenth day, and went home well in a fortnight.

Case II., 1892. A widow aged seventy-four. A large, well-defined cystic tumor was discovered to be the cause of the prominence of the abdomen, which was larger than a full-time pregnancy. On August 6th, 1892, the author removed a large cystic ovarian tumor free from adhesions. The after progress was uneventful. On the ninth day the dressings were taken off for the first time and the sutures taken out. The wound had entirely healed by first intention. On the fifteenth day the patient went home well.

Case III. A widow aged seventy-two. On September 8, 1892, the author performed the following operation. A flaccid cyst of the right ovary containing about one gallon of very thick glairy fluid was removed. The left ovary, with a hard tumor about the size of a walnut growing from it, was also taken away, and the abdominal wound entirely closed. Subsequent progress was most satisfactory. The dressing was changed for the first time on the tenth day after the operation, when the stitches were taken out. The wound healed by first intention except at one place about half an inch long, where the skin had become inverted and granulations were visible. This healed a few days afterwards. On the tenth day the patient left her bed, and on the fifteenth she went home.

Case IV. A widow aged seventy-seven. She had never been robust, but usually healthy. The patient was a thin, dark woman, who looked ill, with high temperature, tender swollen abdomen and œdematous legs; the right leg was more swollen than the left. An operation was performed on Sept. 20 ,1892. On opening the abdomen in the right linea semilunaris, an ovarian tumor the size of a football was exposed and removed. No pus was found. The cæcum was adherent to the parietes, and a fluid collection could be felt behind and to its outer side extending back to the loin.

A second incision above the center of the crest of the ilium allowed the escape of fully six ounces of fetid pus. The anterior or ovariotomy wound was sutured and the lateral wound drained with a glass tube, each wound being separately attended to and dressed. The ovariotomy wound never gave any trouble and quickly healed. Until October 8th, the after progress was most satisfactory; the general condition improved, with return of appetite, sleep and freedom from pain. On this date the glass-tube could not be replaced by the nurse, Dr. Munro, or the

author, and for the first time since the operation her evening temperature was over 100°. October 9th: No discharge from sinus; evening temperature 103°. 12th: A gush of pus from sinus with lowered temperature. Recurrence of a similar sort took place till October 20th, when a fresh tender lump was noticed. 25th: Under chloroform I freely opened an abscess which extended from the iliac crest to the costal margin. The cavity appeared to be between the muscles of the abdominal wall and contained about four ounces of pus. Improvement followed and the patient was able to be out of bed. Soon, however, she relapsed, with some evening rise of temperature. November 5th, Dr. Munro suspecting a further collection of pus, he explored again under chloroform and found pus at the bottom of the first sinus in a large cavity. A counter-opening was made in the back; two full-sized india rubber drainage tubes were passed from the front openings through it, and the cavity was irrigated. The patient never fully rallied and died on November 9th, 1892.

The following is extracted from Dr. Munro's post mortem report. An abscess cavity extended from the anterior surface of the bladder, which was covered with pus, outside the peritoneum, along the iliac fossa, and upwards to the under surface of the liver. The three openings made at different times all led into one cavity. The second abscess cavity was between the *obliquus internus* and the *transversalis* muscles. No communication between the abscess sac and the peritoneum could be discovered, but from eight to ten ounces of pus were found in the pelvis, and the intestines were glued together with purulent lymph. The cæcum and a portion of the ascending colon and ileum, with some surrounding tissue, were sent to the author for dissection. The appendix vermiformis was glued to the posterior surface of the cæcum and the ascending colon. About half an inch from the cæcum it was perforated by a ragged ulcer. The perforation opened into the abscess cavity. The ulcer had nearly cut off the distal from the proximal end of the appendix. Both portions were pervious. No concretion was found.

Case V. A woman, aged 70. She complained of painful swelling in her bowels, and weakness. Three weeks before admission, a painful tender swelling was discovered by Mr. Martin on the right side. Some diarrhœa was the only other symptom. A mass on the right side softened, showing a tendency to point. On Sept. 1st, 1892, the author opened the abdomen in the middle line and introducing his hand, found the bulk of the tumor to be a retro-peritoneal malignant mass surrounding and involving the cæcum. The pointing swelling was now punctured with an hypodermic needle in the right iliac fossa, and pus was discovered. The median wound was closed and dressed, and a drainage-tube left in a separate opening for the abscess cavity. The patient was returned to bed apparently no worse for the operation. The median wound healed in three weeks without any trouble. During September and the first half of October she improved in condition, though profuse suppuration continued, and she was once out of bed. Then symptoms of increased cardiac failure showed themselves in breathlessness and œdema of the legs. On October 30th, 1892, she complained of pain in the left leg, which was noticed to be discolored at its most dependent parts by post-mortem-like lividity. On the day following, some of these reddened patches had turned black, and there was no sensation in the foot and leg, nor pulsation in the arteries. On Nov. 2nd, in the evening, she died somewhat suddenly. Before death total gangrene of the leg had occurred. Necropsy: There was contraction of the mitral orifice of an hypertrophied heart. No vegetations were detected on any of the valves. The left femoral artery was blocked for about six inches with an adherent blood-clot, white in the center and red at the ends. There was a large, malignant mass of glands behind the cæcum and surrounding it. The interior of the cæcum was extensively ulcerated, the ulcer having thick, hard walls. At the outer side and behind the cæcum and ascending colon, a large abscess cavity, extending from the pelvis to the under surface of the liver and diaphragm, was found. No secondary deposits were observed. Examined microscopically the growth proved to be a cylindroma.—*London Lancet*, Jan. 21st, 1893.

A dust of bicarbonate of soda will soothe a toothache.

TETANY AS A SEQUELA OF PUERPERAL ECLAMPSIA.

S. W. Wheaton reports a patient, a primipara, aged twenty who was seized with convulsions immediately after the expulsion of the placenta. In about four hours there had been thirteen attacks. The patient was comatose at that time and with dilated pupils. The conjunctival reflex absent, respiration rapid and irregular, and crepitations were heard at the bases of both lungs. Temperature 100°, pulse 150, feeble but incompressible. A few drachms of urine drawn off with catheter were found solid with albumen and contained blood, blood casts and ½ per cent. of urea. Wet cupping to both loins; one eighth of a grain of hydrochlorate of pilocarpin was injected subcutaneously; twenty grains of chloral and a drachm of bromide of potassium were given per rectum. In an half hour another convulsion of a typical epileptic character occurred, preceded by a sighing sound and a marked contraction of the uterus. The wet cupping and pilocarpin injection were repeated and were soon followed by a profuse diaphoresis. Only four attacks occurred, during the next thirteen hours. She was however still unconscious, but could swallow; conjunctival reflex had returned, and temperature rose to 103°. Liquor Ammoniæ Acetatis was given, two drachms every two hours, and also a purge and an enema. The secretion of urine increased, the albumen diminished and the urea increased. There were no signs of further lung mischief but a systolic murmur appeared at the apex of the heart, with no increase in its area of dullness. On the third day after confinement, while still unconscious she had spasmodic attacks of rigidity of the limbs; the ankle-joints extended and the toes adducted; the jaws rigid and pressure on the limbs caused increased rigidity.

This condition, which was thus typical of tetany lasted three days, after which it gradually disappeared, consciousness returning slowly; temperature became normal; the urine increased in quantity; there was complete loss of memory regarding events preceding the fits; secretion of milk was entirely absent but the involution of the uterus proceeded normally. Convalescence was complete in three weeks. Six months later the urine contained still a trace of albumen.

The author further states that tetany always occurs after some cause producing exhaustion or defective nutrition of the nervous system. Especially is this the case in the easily-exhausted nervous system of children, in whom tetany is so common as the so-called "carpo-pedal contractions." These contractions may follow convulsions, diarrhœa, teething or any exhausting cause. In adults tetany principally occurs in women, especially from the exhaustion of lactation or pregnancy under unhealthy surroundings, as also in connection with hysteria as in a case reported by Dr. Caiger, (*The Lancet*, Aug. 20, 1887). Tetany may be regarded as the result of profound exhaustion or mal-nutrition of the higher motor centers of the cerebral cortex, in consequence of which the restraining influence is withdrawn from a lower stratum of cells, which are thus allowed to come into action without any regulation from higher centers. The normal action of this lower stratum of cells is to initiate movements corresponding to the typical attitudes of this disease, consequently when the higher control is withdrawn their uncontrolled action produces permanent contractures. In the case in point, the exhaustion of the higher centers was due to the repeated convulsions, and its intensity was marked by the long period of unconsciousness and absence of voluntary movement; also by the persistent high temperature, which latter is also probably due to the unregulated action of lower heat-producing centers, owing to the exhaustion of higher controlling ones. That no organic lesions exist in tetany is proved by the fact that it may recur in the same subject again and again at intervals. The cardiac murmurs were undoubtedly due to anæmia, although at the time they gave rise to a suspicion of ulcerative endocarditis. This is frequently seen as a result of septicæmia after delivery, to which cases of eclampsia are particularly exposed owing to the failure of antisepsis in patients with convulsions and suffering from involuntary evacuations. Another point of interest is the increase in the amount of urine and urea which followed measures for the relief of kidney congestion. No treatment was ordered

for the tetany except quinine and iron; it is essentially a symptom of deficient action of the nervous centres and requires a tonic treatment. Dr. Dakin has collected eight cases of tetany during pregnancy (*Obstetrical Society's Transactions*, vol. xxxii., p. 163); they all occurred before delivery—not after, as in the present case—and one ended fatally.—*London Lancet*, Jan. 28, 1893.

SELECTED FORMULÆ.

Worm Powders.

C. W. Moister.

℞
Santonin ..... 10 grains.
Calomel ..... 15 "
Scammony, resin, powdered 15 "
Powdered sugar ..... 30 "

Mix, and divide into 15 powders. Give one three times daily (on an empty stomach) for one day and repeat in three days if necessary.

C. W. Moister.

℞
Santonin ..... 10 grains
Podophyllin resin ..... 4 "
Powdered rhubarb ..... 15 "
Sugar of milk ..... 30 "

Mix, and divide into fifteen powders. Give powders 5 hours apart (on an empty stomach) until three have been given.

Omit a day, repeating the dose if necessary.

—*Ex.*

Typhoid Fever in Children.

Dr. Earl (Arch. of Pedriat.) gives the following as nutritious, aiding digestion, and a mild intestinal antiseptic:

℞
Pepsin cordial ..... ʒ i.
Syr. hypophos. comp. ..... ʒ iv.
Acid. sulphur. arom ..... ʒ i.
Aquæ menth. piper., q. s. ad ..... ʒ ii.

M. d. Sig.—One teaspoonful, well diluted, four times daily.

—*Ex.*

Santonin Lozenges.

℞
Santonin ..... 5 gr.
Pulverized sugar ..... 3 dr.
Pulverized acacia ..... 8 dr.
Mix well and add:
Mucilage of acacia ..... 16 drops.
Water, a sufficient quantity.
Make into 10 lozenges.

—*Phar. Era.*

Diphtheria.—(Local Treatment.)

—PAINT.—

℞
Citric acid (cryst.) ..... 3-4 "
Carbolic acid (cryst.) ..... 3-4 parts.
Iodine tincture ..... 5 "
Cognac ..... 100 "

Apply every two hours by means of a cotton tampon.

—*Ex.*

In Syphilitic, Oral, Lingual and Pharyngeal lesions.

(Dr. G. Frank Lydston)

℞
Carbolic acid ..... gr. 10
Iodide ..... " 5
Menthol ..... " 10
Oil of eucalyptus ..... dr. 2
Glycerole of tannin ..... " 2
Boroglyceride, enough to make. oz. 1

Label: Apply with a brush.

—*Western Druggist.*

Thymol and Salicylic Acid Against Fœtid Breath.

—MOUTH-WASH.—

℞
Thymol ..... 1 part.
Borax ..... 2 parts.
Alcohol ..... 4 "
Distilled ..... 2000 "

Externally!—Use several times daily.

or:

℞
Salicylic acid ..... } of each, 1 part.
Saccharin ..... }
Sodium bi-Carbonate ..... }
Alcohol ..... 30 parts.

Mouth-wash!—Teaspoonful to a glassful of water, several times daily.

—*Journ. de Med. de Paris.*

For Toothache

Take of:—

℞
Menthol ..... 36 grains.
Chloroform ..... 1 drachm.

Mix, and after the cavity of the tooth is cleansed apply a few drops on a piece of cotton wool.

—*Ex.*

Fissure of the Nipples.

℞
Salol ..... dr. 1
Cocaine hydrochlorate ..... gr. 2
Ether ..... fl. dr. 2
Collodium ..... fl. dr. 4

—*Am. Pract.*

Worm Syrup.

Ch. and Dr.

℞
Fluid extract of spigelia ..... 5 ozs.
Fluid extract of senna ..... 3 ozs.
Oil anise ..... 10 minims.
Oil caraway ..... 10 "
Syrup ..... 8 ozs.
Mix.

Dose—One or more teaspoonfuls at intervals until purging commences.

—*Ex.*

Ringworm.

℞
Oleate of Copper ..... ½ drachm.
Benzoated Lard ..... 1 ounce.

Mix; the ointment to be applied night and morning.

—*Pop. Med. Month.*

Prophylactic for Tonsillitis.

The following is recommended for use by those persons predisposed to the development of tonsillitis (*Clin. Jour.*):

℞
Olei. menth. pip ..... mviij.
Acid. carbolic (crystal) ..... ʒj.
Spt. vini. Rectificat ..... ʒij.

M.

Sig. Ten drops to be added to a cup of warm water, and this solution to be used as a gargle night and morning.

—*Ex.*

Nervous Debility.

℞

Acid phos. dilut.,	ʒ 4.
Calisayæ elix.,	ʒ 2.
Elix. valerian ammon.,	ʒ 1.
Glycerine,	ʒ 2.
Vini xerici, q. s.,	ʒ 8.

M. Sig.—Tablespoonful in water three times a day.

—*Ex.*

Dusting Powder for Children.

℞

	Parts.
Burnt alum	15
Boracic acid	15
Precipitated calcium carbonate	150
Starch	250
Carbolic acid	3
Oil of lemon, a sufficient quantity.	

—*Ex.*

A simple yet efficient prescription for allaying the craving for drink in dipsomaniacs is as follows:

℞

Tr. capsici	m x.
Tr. nucis vom	m x.
Ac. nitric dil	m xx.
Aquæ	ʒ ii.

M. Sig. This quantity to be taken three times a day.

—*Cincinnati Lancet.*

Anal Fissure.

Allingham strongly advocates the use of the following ointment:

℞

Hydarg. subchlor	gr. iv.
Pulv. opii	
Ext. belladonna	aa gr. ij.
Ung. sambuc	ʒj.

M. Sig.: To be applied frequently.

—*Ex.*

Syphilitic Ulcers.

Dr. Mauric prescribes an ointment composed of:

℞

Hydrarg. chlor. mitis } Zinci oxidi }	aa grs. xv.
Petrolati	ʒvj.
Pulv. amyli	grs. xlv.

M. ft. ungt

—*Ex.*

Iodated Water in La Grippe.

Dr. G. J. Muller (*Wiener Med. Presse,*) has administered iodine with good results in the grippe. The action of the remedy is noticeable, at the latest, twenty-four hours after its administration. It acts best in painful cases, with colic, etc. Aqua iodata is a solution of iodine in 5000 parts of water. The solution should be freshly prepared every time it is taken. One may prescribe:

℞

Tinct. iodine	2 gms. (gtts. xxx)
Alcohol	40 gms. (ʒjss.)

Five drops twice a day in half a glass of water. Sugar may be added to the water; every other addition is to be forbidden.

Substitute for Mother's Milk.

The following is claimed to be almost exactly identical with normal woman's milk in composition:

℞

Cow's milk	1 pint.
Water	¾ "
Cream	5 tablespoonfuls
Milk Sugar	3 "

—*Exchange.*

Expectorant.

The best remedy to loosen expectoration is muriate of ammonia, combined with some such remedy as syrup of squills. If dry plastic pleurisy be present, iodide of ammonium should be added as follows:

℞

Ammonii muriat	ʒ iiss.
Syr. scillæ	ʒ ij.
Ammonii iodidi	ʒ iss.
Glycerini	ʒ ss.
Syr. prun. virg., q. s	ad ʒ iv

M. Sig.—ʒ j every three hours in water.

At the same time in a case of pleurisy, to prevent any possible tubercular tendency, give something to build up tissue and aid general strength; something to strengthen the chest. The best thing for this purpose is the syrup of the hypophosphites, ʒ j three times a day after meals.

—*Exchange.*

Liniment of Subacetate of Lead.

This sedative and cooling application to burns is a mixture of 40 parts of solution subacetate lead and 60 parts cotton seed oil.

For Painful Hæmorrhoids.

(Lancet-Clinic.)

℞

Ext. of krameria	dr. 2
Cocaine hydrochlorate	gr. 8
Oil of eucalyptus	m. 12
Cacao butter	enough.

Make into twelve suppositories.

Boschee's German Syrup is said to have the following formula:

℞

Oil of tar	1 part.
Extract of ipecac, fld.	4 parts.
Extract of wild cherry, fld	6 parts.
Tincture of opium	4 parts.
Magnesium carbonate	3 parts.
White sugar	80 parts.
Distilled water	48 parts.

Triturate the magnesia and the oil of tar together, mix the fluid extracts and the water, and triturate the whole with the oil of tar and magnesia. Filter, add the sugar and dissolve in the cold by agitation.

—*Nat. Druggist.*

Scrotal Eczema.

℞

Hydrarg. chlor. mit	ʒi.
Zinci oxidi,	grs. 40.
Bismuthi subnit	ʒ 1½.
Lanolin	ʒ 1.
Vaseline	ʒ ½.

M. Ft. ungt.

Sig.—Wash the scrotum in hot borax water, and apply the ointment night and morning.

—*Ex.*

Wash for Pruritus.

℞

	Grammes.
Menthol	4
Alcohol	30
Water	60
Diluted acetic acid	120

Wash with this instead of with plain water.

Applications for Burns.

A German hospital surgeon recommends (*Munch. Med. Woch.*) the following:

℞

Linseed oil	ʒiv.
Lime-water	ʒiv.
Thymol	gr. vj.

Dissolve the thymol in the oil before adding the lime-water.

CURRENT LITERATURE REVIEWED.

THE AMERICAN GYNECOLOGICAL JOURNAL for December contains an article by Dr. Charles P. Noble on

Early Diagnosis and Operation in Cancer of the Uterus.

The author urges the importance of early diagnosis, while the disease is limited to the cervix or the body of the uterus and before the tissues surrounding the uterus have become involved. After involvement of the parametrium a cure becomes impossible. The classical symptoms of hemorrhage, discharge and pain are discussed, and hemorrhage following sexual intercourse is pointed out as a sign of great value in the early diagnosis. "Whenever this occurs, the case should be thoroughly investigated." The old teaching that women approaching the menopause are subject to flooding is, in the author's opinion, most dangerous and the cause of so many cancers reaching the stage of ulceration before discovery. "Especially when women have ceased to menstruate and again have a metrostaxis, should the case be carefully studied." An offensive discharge is present in the ulcerative stage of all cancers, while cauliflower growths give rise to a watery discharge at a much earlier period. Pain is present late in the disease and is due to the involvement of neighboring tissues, peritonitis, etc. The diagnosis of cancer is made from the physical signs aided, if necessary in doubtful cases, by microscopical examination of a portion of the suspected tissue. Papillary and cauliflower growths are easily recognized by the excrescences on the cervix. In its early stage, epithelioma of the cervix may be confounded with the results of inflammation, but "when a definite area in the cervix is hard, infiltrated, and constitutes a distinct mass or tumor in the cervix, it is probably cancer and should be examined microscopically." After ulceration has taken place the diagnosis is easy, and the only conditions liable to be mistaken for it, chancre or gummata, are rare. The author reviews the treatment by curetting, caustics, amputation of the cervix and total extirpation; and decides in favor of total extirpation, as, up to the present, that has given the best results. tatistics are given proving this.

[It is of interest in this connection to note that one operator* recently stated that he had removed cancerous uteri in several instances from virgins, thereby refuting the teaching that the disease is the result of injuries received in childbearing.—Ed.]

Dr. Charles N. Smith reports a case of

Appendicitis

in a child six and a half years old, who, after eating a pint and a half of peanuts within twenty-four hours, presented the classical symptoms of appendicitis—constipation with vomiting, distention and tenderness of the abdomen, especially over McBurney's point. Castor oil was given, causing free evacuations of the bowels consisting mainly of masses of undigested peanuts. The patient improved for a time but, three months later, her condition became such that removal of the appendix was imperative. At the operation the pelvic viscera were found glued together by recent, soft adhesions and a small quantity of flaky pus appeared as soon as the peritoneal cavity was opened. The peritoneal coat of the cæcum had sloughed off over an area $1\frac{1}{2}$ inches long by $\frac{1}{4}$ to $\frac{3}{4}$ of an inch wide. The appendix was found adherent to the cæcum and inclosed in a small cavity formed by adhesions and filled with pus, perforated at its tip and containing a hard, foreign body and a small quantity of liquid fæces. Its peritoneal coat was necrotic. The appendix was ligated and removed, all adhesions broken up, the abdominal cavity flushed, a glass drainage tube passed into the pelvis and iodoform gauze packed against the necrotic intestines and mesentery. The patient did well till the fifth day when a bronchitis developed which extended to the smallest bronchial tubes and the patient died of capillary bronchitis on the sixteenth day. At the autopsy, the abdominal wound was found entirely healed. In the author's opinion, death was caused by the capillary bronchitis and was in no way due to the operation.

Dr. T. J. Crofford, in a paper on "Laparotomy as a Diagnostic and Prognostic Measure," shows the difficulty of always making an exact diagnosis in pelvic troubles, fortifying his position by the report of several cases. These cases illustrate the impossibility of appreciating dangers which may exist in the cases one often meets, by any means short of abdominal section. "Abdominal section *per se*," he says, "under modern methods, is attended with the minimum amount of danger. It is the intra-abdominal condition demanding the section which gives rise to the mortality."

A similar paper is that by Dr. A. V. L. Brokaw on

Experiences in Pelvic Surgery.

He confesses that, with increasing experience in pelvic disease, he finds himself well satisfied with an approximate diagnosis. The diagnosis of pus cases is usually clear, though he has operated for pus and found an extra-uterine pregnancy and *vice versa*. Only those, he says, without operative experience, or the theorists, always made correct analysis of their cases. Much of his work comes from the hands of the routine gynecologist "who treats all of his cases alike—introduces a speculum, paints the cervix with iodine, makes application to the cervical canal or within the uterus itself, insufflates some boracic acid, introduces a glycerine tampon and requests the patient to come again in two days." Much of his work comes to him after the methods of "gynecological tinkering" have been exhausted. In one condition

*Dr. Joseph Price.

above all others exploratory incision should be adopted, namely: suspected extra-uterine pregnancy. It will not do to wait for the positive classical symptoms. They may come and come too late to save the patient. He advocates rapid operating in the dorsal position; a short incision; the drainage tube in nearly every case and the free use of hot water douching of the abdominal cavity. The paper includes the report of a case illustrating his views.

Dr. John Milton Duff contributes a paper on "Post-partum Hemorrhage." This he considers avoidable if proper precautions are taken, and the obstetrician should always be prepared to meet the emergency. The routine administration of ergot at the close of the third stage, he considers pernicious. It should be given only on a clear indication. Vinegar will not always control hemorrhage and he has seen cases in which it was useless. Should the hemorrhage occur from a torn cervix or vagina, the rent should be sutured or, if that is impossible, the cervix and vagina tamponed. He recommends tamponing the uterus with iodoform gauze in bleeding from the placental site. In such an accident, tamponing the vagina is worse than useless.

Dr. Lucy J. Utter reports several interesting "Cases seen in Practice," especially one where an unmarried woman was delivered of twins, one of whom had a very dark complexion and curly black hair, while the other was of light complexion with red hair. The woman confessed to having had intercourse with two men within twenty-four hours, one a very dark man and the other a very light one.

THE KANSAS CITY MEDICAL INDEX FOR FEBRUARY.

Dr. John Ridlon, of Chicago, and Robert Jones, F. R. C. S., of Liverpool, Eng., discuss "Operative Measures in the Treatment of Spondylitis" and describe the various operations for the relief of abscess due to spinal caries. The authors prefer the injection into the abscess cavity, after evacuation, of an emulsion of iodoform to the solution of iodoform in ether formally advocated. An expectant rather than an operative treatment of abscess in Pott's disease is advocated. The article is illustrated by wood cuts explanatory of the paper.

Dr. Emory Lanphear, in an article on "Cancer of the Stomach," urges the importance of early diagnosis and operative interference, presenting statistics on the subject.

Dr. A. H. Colvard contributes a paper on

Diphtheria,

reporting a number of cases to prove that this disease, whice he holds to be primarily local, can be arrested in its earlier stages. He urges that every case of tonsillitis or sore throat occurring during an epidemic of diphtheria, should be treated as diphtheritic. He recommends the use of a mixture of tr. ferri chloridi, potassium chlorate, and hydrochloric acid, reasoning that the chemical reaction will produce free chlorine in its nascent state. The mixture is given every two hours combined with the use of a gargle of mercuric chloride dissolved in hydrogen peroxide.

Dr. B. F. Fortner discusses "Pyosalpinx" and shows that other causes besides gonorrhœa can be responsible for the disease. Often it is due to a post-partum septicæmia. "Laparotomy as early as the diagnosis can be made is the only rational treatment." Electricity ought not to be expected to dispel a quantity of securely pent up pus. Catheterization of the Fallopian tubes he regards as useless and obsolete.

Dr. Fred Byron Robinson describes "Dr. Franklin H. Martin's New Operation of tying the Uterine Arteries for Bleeding Fibroids." An incision is made in the vagina on each side of the cervix and the uterine artery tied by a ligature passed through the broad ligament on each side, by means of a strong curved needle. The incisions are then closed. The advantages and objections to the operation are stated.

Other papers in this issue are: "Protracted Parturition" by Dr. William B. Dewees; "A Case of Malignant Peritoneal Cyst" by Dr. J. M. Baldy, which was originally reported to the Obstetrical Society of Philadelphia and published in the abstract of the society's proceedings in THE MEDICAL AND SURGICAL REPORTER for Oct. 29, 1892, page 692; and a lecture by Reginald Harrison, F. R. C. S., London, Eng., on "Prostatic Obstruction" which is taken from Wood's Monographs.

THE MONTREAL MEDICAL JOURNAL

for February contains a paper by Dr. H. H. Chown on

Enterectomy for the Cure of Fæcal Fistula.

The history of the case of fæcal fistula reported is unique. The patient, a poor widow, living twelve miles from a doctor, had for years a lump in the left groin that appeared and disappeared and gave her no discomfort. She had never shown it to a doctor, but the reporter has little doubt that it was a small inguinal hernia. A fall converted the hitherto reducible hernia into an irreducible one. There were no symptoms of obstruction but, on account of the pain and the presence of the tumor, she decided to deal with it surgically on her own account. She therefore made an incision with a razor into the tumor, and succeeded admirably in performing a left inguinal enterotomy. Two months later she was admitted to the Winnipeg General Hospital, where the author operated on her for the closure of the artificial anus following the plan of Dr. Abbe, of New York. The bowel was divided and each cut end inverted and closed with a fine silk suture. The ends of the bowel were then drawn past each other for the space of six inches and united near the mesenteric line. An incision was then made in each portion of the bowel in such a position as to form a continuous passage for fæcal matter. The two ends of the bowel were then further united by continuing the

mesenteric stitches around the incision in the bowel until they reached their point of origin. The woman recovered perfectly. The author regards the use of decalcified bone plates, catgut rings, etc., as unnecessary.

Dr. R. E. McKechnie reports "An Anomalous Rash in Scarlatina," in which the eruption was papular instead of the ordinary form. The cases were undoubtedly scarlatina, as all the other well known symptoms were present.

Dr. F. H. Menburn reports a case of "Tubal Pregnancy," in which the rupture took place between the second and third month. The patient at first refused operative interference, but later consented. The operation was undertaken too late and the patient died twelve hours after the laparotomy.

Dr. J. G. Adami contributes an article on "Modern Pathology," being an address delivered at McGill University. The subject of modern bacteriology is entered into fully, and the results shown of experimentation on the lower animals as to the production of disease.

Dr. T. J. Harrison in his "Address on Obstetrics," delivered before the Canadian Medical Association, considers the use of the forceps in labor; and Cæsarean section vs. craniotomy. He advocates the early use of the forceps and craniotomy, rather than the Cæsarean operation.

EDINBURG MEDICAL JOURNAL.

The February issue contains a carefully prepared paper by Dr. Halliday Croom on "Premature Sexual Development in Relation Specially to Ovarian Tumors, with an Illustrative Case of Ovarian Sarcoma in a Child of Seven; Laparotomy; Recovery."

Precocious menstruation with associated premature sexual development, although by no means unique in its occurrence—as the medical literature of this country and of Europe attests—is yet of sufficient rarity to invest it with at least a transient interest to the observer when such an anomaly does present itself. After a careful perusal of the available literature the writer tabulates the cases found under the following heads:

1. Precocious menstruation with an early appearance of the external manifestations of puberty.
2. Sexual development with menstruation.
3. Menstruation previous to development of the sexual organs.
4. Early conception and pregnancy.
5. Premature sexual development associated with tumors of the generative organs.

Dr. John Wyllie in a continued paper entitled "The Disorders of Speech," under the heading "Speech in its Relations to Diseases of the Nervous System," considers:

1. Speech in its relations to insanity.
2. Illustrations of the manner in which language mirrors the condition of the mind.
3. The action of the speech centres in insanity.

Dr. David Wallace in his paper "Tumors of the Bladder" offers the following conclusions:

1. Tumors in the bladder are now known to be of more frequent occurrence than was formerly supposed.
2. The history of hæmaturia and its character may be strongly indicative of the presence of a tumor.
3. Positive evidence of the presence of tumor by the detection of portions of the tumor or characteristic cells is seldom obtained from the urine.
4. Cystoscopic examination, although not always possible, in the majority of instances enables one to detect the tumor when present.
5. With the cystoscope one is enabled to tell the site, size and superficial attachment of the tumor and approximately its character.
6. No evil results attend the use of the cystoscope.
7. Tumors in many cases can be thoroughly removed from the bladder.
8. Suprapubic cystotomy gives the best access to the bladder.
9. The proportion of malignant tumors as compared with benign is very high.
10. Sufficiently good results follow the removal of malignant tumors to justify operation.

THE PACIFIC MEDICAL JOURNAL

for February contains three papers: "A Case of Trephining in Epilepsy" which occurred in the practice of Dr. C. N. Ellinwood and is reported by Dr. Frank Fischer. The patient had received a hard blow on the head when a boy, which was followed by epileptic seizures, particularly marked on the right side. A button of bone was removed from the left side of the skull corresponding to the region of the hand centre. No disease of the brain substance was found though the bone was slightly thickened at this point. The patient recovered from the operation and during the six months which have elapsed has improved, though the attacks continue, but at longer intervals than formerly.

Dr. C. G. Kenyon discusses the operative treatment of "Empyema" by exsection of the sixth or seventh rib, or both, and thorough drainage of the pus cavity. The object of the exsection is to allow the chest wall to collapse and thus bring the sides of the abscess cavity into apposition.

The remaining paper is "Recent Discussions respecting Bacteria" by Dr. J. H. Wythe, in which the recent utterances of authors on the bacterial causation of disease are given in abstract.

THE WOMAN'S MEDICAL JOURNAL

for January contains an article by Dr. Mary Putnam-Jacobi on

Permanent Drainage in the Treatment of Endometritis.

in which she advises the introduction into the uterine cavity, under antiseptic precautions, of an aluminium drainage tube for the relief of this affection. Antiseptic douching

and intra-uterine packing around the drainage tube were also included in the treatment of the two cases reported.

The other paper in this month's issue is by Dr. Elizabeth Woods on Chronic Metritis and Endometritis. The various methods of treatment advocated by different authors are summarized. As the writer of the paper confesses, she has no new facts to communicate.

[The journal makes its appearance for the first time. this being the initial number. It is edited and published by women and therefore should appeal strongly to them for support.—Ed.]

PERISCOPE.

THERAPEUTICS.

Quinine Tannate.

"Of the various compounds of salts of quinine met with none have perhaps received less recognition than the tannate, says Dr. A. C. Zeig. Whether it be due to a misconception of its therapeutic value, the writer is unable to state.

On examining various samples of this compound they were found to vary both in their physical properties and in the per cent. of quinine alkaloid in combination, the latter varying from 10 to 25 per cent. Natural quinine tannate is an amorphous grayish powder, odorless and tasteless, soluble to a small degree in cold water, soluble in alcohol, and but slightly soluble in ether. Owing to the objection raised against the more common and soluble of quinine salts this most peculiar compound often meets with favor when it is the intention of the prescriber to employ an article that will not offend a sensitive palate.

It has been questioned by some writers on this same subject as to whether tannic acid, by reason of its chemical structure and by the nature of its behavior toward reagents, is capable of forming a true compound with quinine similar to those of inorganic and organic acids containing displaceable acid hydrogen. Tannin, as we are well aware, is the anhydate of gallic acid, and, like many anhydric oxides of its kind, is incapable of becoming hydrated by mere contact with water. It needs the intervention of other agents, as bases, acids or ferments, reinforced or aided by influence of heat.

For preparing the compound from the more common form of quinine, namely, the sulphate, the following formula may be recommended:

℞

Quinine sulphate	40 parts
Sulphuric acid dilute	40 parts
Tannic acid	90 parts
Sodium bicarbonate	10 parts
Sodium acetate	10 parts
Distilled water	q. s.

Dissolve quinine sulphate is 2000 parts of distilled water, with aid of the dilute sulphuric acid. Dissolve sodium bicarbonate of and sodium acetate in another 2000 parts of distilled water. When dissolved add to it the tannic acid, and triturate until complete solution is effected. Add the quinine sulphate solution to tannic acid solution, stirring the mixture while it is being added. Set aside for six hours, stirring it at intervals, after which the precipitated tannate may be transferred to a wetted filter and washed. After draining it should be dried between bibulous paper at a temperature not exceeding 140° F. The resulting tannate of about 50 to 55 parts represents between 25 and 30 per cent. of anhydrous quinine alkaloid, equivalent to about 35 to 36 per cent. of the sulphate. Owing to incomplete combination taking place while the solutions are being mixed, it is quite important to let the mixture stand some hours before filtering. The bicarbonate and acetate of soda which, although they do not enter the product, facilitate the combination as well as filtration to a large degree, and may therefore be regarded as a valuable adjunct to the process. It should be borne in mind, however, that on too long digestion or contact with water, partial or complete conversion of the tannate into the soluble gallate may result, in which instance the compound has a decided bitter taste, and, furthermore, that when the compound be left in contact with saliva upon the tongue for some time a slight bitterness is perceptible, caused by the action of the alkaline saliva upon the same, while the bitter sensation of taste is altogether dependent upon the degree of alkalinity of the latter, thus varying in different individuals.

The compound is especially adapted for administration to infants and invalids, particularly those of the gentler sex who are afflicted with delicate digestive organs. The most agreeable method of administering this remedy is in the form of compressed tablets in which sugar and chocolate are made to act as adjuvants and render this pharmaceutical very acceptable, so that in place of displeasure or indifference we find these tablets really enjoyable. As offered by most manufacturers each tablet is made to contain one grain of quinine tannate, holding in combination 25 per cent. of quinine alkaloid.—*Phar. Record.*

Poisoned by Strychnine.

Twenty grains of strychine sulphate was swallowed by mistake by an Englishman, who was saved by the treatment inaugurated ten minutes after the accident. The poison had been taken on a full stomach. Emesis was induced by hypodermic injections of apomorphine and mustard and salt by mouth, which was followed by the stomach pump. The antidotal treatment consisted in the administration of tannin, chloral and bromides.

Piperazin.

Drs. Biesenthal and Schmidt review (from the *Berliner Klinische Wochenschrift* in *Therapeutic Gazette*) the clinical reports on piperazin which have appeared recently. The reports of Vogt, Ebstein, Heubach, Krakauer and Brik, all based on the use of Schering's Piperazin, are all very favorable. Testimony seems to be nearly unanimous that the remedy is harmless, and that it is effective as a solvent of uric acid. Biesenthal and Schmidt report seven cases in which the remedy has been tried. Four of the cases are given in detail. In three of the latter, who were gouty patients, and had attacks of gout, marked relief was obtained. The fourth patient had violent attacks of renal colic. On the first day the piperazin was used an extraordinary quantity of gravel was passed. After the second dose, on the next day, large quantities of gravel were passed several times, and almost immediate relief was experienced. Similar results were obtained in other cases. Biesenthal and Schmidt recommend the remedy very highly. Internally, they say, piperazin is best given in dilute solution in doses of fifteen grains distributed during the day. Its taste is very slight. As it is not irritating to mucous membranes, a one or two per cent. solution may be employed in washing out the bladder in the case of vesical calculi. Hypodermic injections into gouty deposits and local applications to gouty swellings may also be employed.

MEDICINE

Chronic Pulmonary Phthisis in Later Adult Life.

Dr. H. W. G. Mackenzie says :

The disease, while relatively less frequent than in early adult life, is still not uncommonly met with.

It more commonly attacks males than females.

The influence of heredity although less marked, can still be traced in some of the cases.

The disease is essentially chronic in form.

It is in a considerable number of cases limited to one lung.

Tubercular disease of the larynx and intestines is found in as great a proportion of the fatal cases as in earlier life.

The onset is usually insidious.

Cough, with emaciation and debility, should always suggest the possibility of phthisis in an elderly person.

Hæmoptysis is less frequent except in the later stages, when there is considerable risk of profuse and possibly fatal hemorrhage.

The symptoms of disease are sometimes quite misleading, being abdominal in type, suggestive of malignant disease, and generally arising from intestinal or peritoneal tubercle.

Sometimes the physical signs are best marked at the apex posteriorly.

Sometimes the disease is complicated with chronic bronchitis and emphysema, which mask the physical signs, and then is easily overlooked unless the sputum be examined for bacilli.

The duration of the disease is essentially protracted, but difficult to determine clinically on account of the gradual onset of the illness.

The maintenance of strength and nutrition, and the quietness of the pulse, are most encouraging as regards prognosis, while the opposite and the occurrence of complications are of grave omen.—*Med. Press and Circular.*

Diet in Obesity.

Dr. Towers Smith gives the following rules :

FIRST PERIOD, FOURTEEN DAYS.

Breakfast : Tea or coffee, with saccharin, if desired, in lieu of sugar ; bread or biscuits made from soya bean, two ounces ; grilled white fish or red meat, kidneys.

Lunch : Cut from joint of beef or mutton, taking no fat, and one helping of green vegetables, avoiding only peas, beans, and all roots ; soya bread or biscuit, one ounce.

Dinner : Clear soup, white fish, red meat, green vegetables as lunch ; soya bread or biscuit, one ounce.

DRINK.

First thing on waking : Tumbler of hot water with slice of lemon.

11 A. M. : Cup of bovril or clear soup.

Lunch : Two glasses of claret or one ounce of whiskey with potash water.

5 P. M. : Cup of bovril or clear soup.

Dinner : Two glasses of still hock or claret, or whiskey or potash.

Bedtime : Cup of bovril or clear soup.

Mustard, pepper, salt, Harvey's sauce, may be taken.

SECOND PERIOD, TWENTY-ONE DAYS.

Addition to No. 1 : Oysters, tongue, stewed fruit, with saccharin ; poultry, game.

THIRD PERIOD, THIRTY-ONE DAYS.

Additions to No. 2 : Toast instead of soya bread, for each meal, two ounces, savery jellies, aspic of prawns, plovers' eggs, jelly.

Dessert : A small quantity of fruit ; blue-mould Dorset cheese.—*Med. Times.*

Croup Treatment.

The employment of turpentine oil having given good results in diphtheritic laryngitis, Dr. Bonain (*Rev. de Lar., d'Otol., et de Rhin.*) was induced to try hypodermic injections of this medicament in two cases of well-pronounced croup, and both cases ended in recovery. He prescribes the following mixture :—

Lactic Acid	3 parts.
Syrup Tolu	50 "
Water	100 "

Half a tablespoonful every hour.

Besides, inhalations — two-hourly — of a teaspoonful of the following mixture were resorted to :—

Carbolic Acid.....1 part.
Alcohol.....} of each 10 parts.
Chloroform.....}

Finally, injections—morning and evening—into one of the supra-spinous fossæ of a syringeful (16 minims) of the following solution, were made :—

Tupertine Oil.....1 part.
Vaselin Oil.....5 parts.

By means of the above treatment, the cure is said to have been obtained, in the one case in seven in the other in four days.—*Merck's Bull.*

SURGERY.

Symphysectomy in Man.

M. Albarran presented a man of thirty on whom he practised first symphysectomy and then removed a large portion of the posterior surface of the bladder. This man was operated on two years ago for a neoplasm of the bladder, removed by the hypogastric incision. A year subsequently the hæmaturia reappeared, and a cystoscopic examination revealed a sessile epithelioma situated near the neck of the bladder. The operation in question was performed in September last. A longitudinal incision was made about three inches above the pubis, and carried down to within half an inch of the root of the penis, where it was terminated by small lateral incisions representing the branches of an inverted Y; the penis being freed from its attachments, an *ecarteur* was placed between the pubis and the bladder. The symphysis was then cut through and the two branches separated an inch and a half; a large section of the lower portion of the bladder was then effected without much difficulty, and the divided surfaces united by a double row of sutures; a catheter *a demeure* was placed. The patient remained seventeen days in an apparatus, and in a short time afterwards he was able to get up. At present he is able to work as usual, and has got very stout.—*Med. Press and Circular.*

A Method of Passing a Sound Through an Apparently Impassable Stricture.

In strictures apparently impassable for a sound of bougie even of the finest calibre, it is recommended (*La Semaine Medicle*, No. 1, 1893) to inject equal parts of a four per cent. solution of cocaine and one of sublimate, 1 per cent., into the urethra, compressing the penis somewhat in advance of the stricture with the thumb and forefinger of the right hand. Then the sound or bougie is introduced, the compression preventing the escape of the fluid. It is said to be astonishing with what ease the instrument will sometimes penetrate. This is probably due to the funnel-shaped distension of the urethra in front of the stricture. Possibly the cocaine contributes to the result, by reducing, to an extent, the congestion of the mucous membrane.

Death Under Chloroform.

Mr. F. Mortimer Rowland, M. B., Resident Medical Officer at the City Infirmary, Birmingham, has forwarded us the following report of a case of death under chloroform in that institution: M. S., aged 57, was admitted on November 9th, under Dr. Carter, suffering from ascites, which was thought to be complicated by a tumor (? cystic) in the right pelvic region, for which it was decided to operate. For this purpose, she was transferred to Mr. Jordon Lloyd; and on November 12th, the heart having been found to be apparently healthy, chloroform was administered on a piece of folded lint. Chloroform was given in preference to ether because of an asserted liability to pulmonary trouble. The patient took the anæsthetic perfectly well, and was in no way excited, respiration continuing evenly and deeply, and at normal rapidity up to the time when the skin incision had been made, when quite suddenly, and without warning, she became livid, made a few shallow gasps, and breathing ceased. The heart was examined instantly, and no sounds could be detected. The pupils were not dilated, being about a line in diameter. The tongue was well forward between the teeth during the administration. The head was lowered over the end of the table, and artificial respiration, both by Sylvester's and Howard's methods commenced, but no air could be made either to enter or leave the chest. Insufflation of the lungs was tried without effect, tracheotomy was then performed and insufflation again attempted, though again without effect. Heart puncture made within a few minutes of the onset of alarming symptoms showed the cardiac muscle to be absolutely inactive. Chloroform from the same bottle had been administered the day previously, and was given to another case immediately afterwards without any disturbing effect. The amount administered in this case was not measured accurately, but could not have exceeded half an ounce, and the patient was completely, but not deeply, under when alarming symptoms arose. It is thought respiration and circulation ceased simultaneously, but that the symptoms were due to respiratory cessation, aided by the upward displacement of the diaphragm from the abdominal fluid. At the *post-mortem* examination the cardiac condition was not such as could be recognized by auscultation, there being no valvular lesions, nor was the condition of the muscles such as could have affected the duration and tone of the first sound. Dr. Rowland calls particular attention to the following: (1) The normal size of the pupils; (2) the position of the tongue; (3) the sudden development of the condition; (4) the lividity of the face throughout in the entire absence of obvious signs of laboured breathing; (5) the early arrest of the heart's action as discovered by auscultation and puncture; (6) the complete failure from the first to make air either enter or leave the chest by any artificial means.—*Brit. Med. Jour.*

In all doubtful cases of injury to the skull, exploratory operation is justifiable.

OBSTETRICS.

The Treatment of Eclampsia.

At the Academie de Medecine M. Charpentier read a paper on the treatment of eclampsia. Every woman, he said, pregnant and albuminuric being exposed to eclamsia, and the milk *regime* producing marvellous results in such cases should be consulted as regards her urine, and when the slightest trace of albumen is detected an absolute milk diet should be ordered as *preventive* treatment. Once the eclamsia declared, bloodletting should be resorted to if the patient be of plethoric disposition. From twelve to fifteen ounces of blood might be removed, and then chloral should be administered. If the woman be delicate and the phenomena of cyanosis but little marked, chloral alone will generally be sufficient. In an obstetrical point of view the following rules are useful to bear in mind: leave to Nature as far as possible the delivery; if the labor be tedious, on account of weak contractions of the uterus, the delivery can be hastened by the forceps, or the cephalotribe if the child be dead. Provoked delivery should be reserved only for exceptional cases, but in any case the Cæsarian operation should be rejected as well as deep incisions into the neck of the womb.

M. Gueniot said that eclampsia consisted of two fundamental elements, poisoning of the blood and excitability of the medullar reflexes. In certain cases the toxic principles play but a secondary *role*, while in others they constitute all the symptoms. In the first case it is frequently sufficient to relieve the woman of the fœtus, or to give chloroform or choral to arrest the attacks. In the second, on the contrary, a cure is very rare, and blood-letting seems to offer the only chance. As to chloroform and chloral he administered in the following manner: He gives the former until anæsthesia is complete, and keeps the patient under its influence in a deep sleep, for five or six hours; it is rare after such treatment that the attacks return. Chloral is more easily employed as it does not necessitate the presence of the attendant constantly at the bedside. It should be given in large doses and in enema so as to avoid the irritating effects on the stomach.

M. Tarnier considered that no matter what kind of treatment is adopted, eclampsia is always a grave malady, consequently the preventive treatment as recommended by M. Charpentier should be rigorously prescribed in every case where albumen is present in the urine.—*Med. Press and Circular.*

The Management of the Placenta in Delivery.

Beaucamp, of Aix-la-Chapelle (*Archiv. f. Gynak.*, vol. lxii, pt. 1, 1892), publishes statistics of 500 labors conducted after Ahlfeld's principle of leaving the placenta two hours' time to come away. He found that the average of flooding was high. In 163 cases where flooding occurred the placenta was discharged spontaneously 89 times before the two hours had elapsed; in 67 cases it had to be expressed. Beaucamp concludes that expression of the placenta should be performed within half an hour, as that practice involves less risk of hemorrhage, nor does Ahlfeld's practice lessen the risks of retention of membranes. This occurred in 102 out of the 500 cases. A very important piece of advice is added to these statistics. Beaucamp urges, contrary to Ahlfeld's opinion, that the midwife must stay with the patient yet two hours more after the delivery of the placenta; for in his 500 cases flooding came on in 12 cases within the first two hours after the placenta had been expelled. Hence, if the midwife be ordered to wait two hours for the placenta, it is a grave mistake not to instruct her to stay yet two hours longer after it is born.—*Ex.*

GYNECOLOGY.

Bleeding Fibroids and Endometritis.

Nitot (*Bull. et Mem. de la Soc. Obstet. et Gynec. de Pasis*, November, 1892) recently removed large bleeding fibroids from two women over 40 years of age. In neither was their any trace of the fungous endometritis to which the bleeding seen in many cases of fibroid has been attributed. In one case the blood was seen oozing from innumerable pores, the dilated orifices of the glands of the endometrium. In the other the mucosa looked perfectly normal. In cases where endometritis exists that disease is a complication or coincidence, but not the cause of hemorrhage. The bleeding is, in Nitot's opinion, caused by the vascularity of the uterus above. Lucas-Championniere, in the discussion on Nitot's specimen, said that the endometritis was exceptional in fibroma. The true cause of the hemorrhage was unknown. It occurred in cases where the myomatous growth lay far from the mucous membrane, and might be absent in cases where the growth was in immediate contact with the mucosa.

Urticaria and Death after Ovariotomy.

Omori and Ikeda (*Centralbl. f. Gynak.*, 1892, No. 52), of Fukuoka, Japan, make note of this case in a series of 100 ovariotomies. The patient was aged 54; the tumor was a small dermoid, universally adherent to intestine and omentum; the pedicle was long, and also adherent to the surface of the tumor. On the morning of the fifth day the temperature rose very suddenly, and the whole body was covered with an eruption having all the characters of urticaria. Death occurred within a few hours. The fatal result was attributed to peritonitis, but the authors of the paper admit that they were doubtful on the point.

ARMY AND NAVY.

U. S. ARMY, FROM MARCH 5TH, 1893, TO MARCH 11TH, 1893.

1st Lieutenant Henry R. Stiles, Assistant Surgeon, U. S. Army, will be relieved from duty at Jefferson Barracks, Missouri, on receipt of this order at that post, and will report in person to the commanding officer, Fort Omaha, Nebraska, for duty at that post.

Captain Marcus E. Taylor, Assistant Surgeon, U. S. Army, will be relieved from duty at Vancouver Barracks, Washington, at the expiration of his present leave of absence, and will report in person to the commanding officer, Fort Logan, Colorado, for duty at that post.

U. S. MARINE HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDING MARCH 3RD, 1893.

Murray, R. D., Surgeon, when relieved, to proceed to Key West Quarantine for duty, March 1, 1893.

Bailhacha, P. H., Surgeon, to proceed to New York., N. Y., for duty Feb. 13, 1893.

Purviance, George, Surgeon, detailed as Chairman, Board of Examiners, Feb. 13, 1893. To inspect Ready Island, Delaware River, February 23, 1893.

Hutton, W. H. H., Surgeon, to proceed to Solomon's Island, Md., as Inspector, Feb. 6, 1893. When relieved to proceed to Detroit, Mich. for duty February 13, 1893.

Hamilton, J. B., Surgeon, detailed Chairman Board to prepare Quarantine regulations, February 16, 1893, detailed as Chairman Board to examine officer Revenue Marine Service, February 28, 1893.

Austin, H. W., Surgeon, detailed as member Board to prepare Quarantine Regulations February 16, 1893.

Gassarrag, J. M., Surgeon, detailed as member Board of Examiners, February 13, 1893.

Godfrey, John, Surgeon, when relieved to proceed to San Francisco, Cal., for duty February 13, 1893.

Irwin, Fairfax, Surgeon, detailed for duty in office of the U. S. Consul, Marseilles, France, February 25, 1893.

Wheeler, W. A., Surgeon, detailed as Recorder Board of Education, February 13, 1893. Detailed as member Board to prescribe Quarantine Regulations, February 16, 1893.

Stoner, G. W., Surgeon, to proceed to Baltimore, Md., for duty, February 13, 1893.

Warden, Eugene, P. A., Surgeon to proceed to Baltimore, Md., for temporary duty, February 23, 1893.

White, J. H., P. A., Surgeon, to proceed to Hamburg, Germany, for duty February 27, 1893.

Carrington, P. M., P. A., Surgeon, granted leave of absence for seven days, March 1, 1893.

Williams, L. L., P. A., Surgeon, when relieved to proceed to Charleston, S. C., for duty February 14, 1893.

Bratton, W. D., P. A., Surgeon, detailed as member Board to examine officer Revenue Marine Service, February 28, 1893.

Kingorm, J. J., P. A., Surgeon, detailed as member Board to prepare Quarantine Regulations, February 16, 1893.

Guitoras, G. M., P. A., Surgeon, to proceed to Gulf Quarantine for duty, February 23, 1893.

Geddings, H. D., P. A., Surgeon, detailed as recorder Board to prepare Quarantine Regulations, February 16, 1893.

Wertenbaker, C. P., P. A., Surgeon, detailed as Recorder, Board to examine officers, Revenue Marine Service.

Condict, A. W., Assistant Surgeon, ordered to examination for promotion, February 14, 1893.

Hussey, S. H., Assistant Surgeon, ordered to examination for promotion, February 14, 1893.

Perry, J. C., Assistant Surgeon, ordered to examination for promotion, February 14, 1893, to proceed to Savannah, Georgia, for temporary duty, February 25, 1893.

Smith, A. C., Assistant Surgeon, ordered to examination for Promotion, February 14, 1893.
